Kiryat Hayovel is a suburb of the city of Jerusalem which is 800 meters above sea level The population of Kiryat Hayovel is about 15000 The social class distribution of the babies in this study population (n=858) by fathers occupation indicates that 19% are social class I+II (the upper classes) 31% social class III$_1$ (white collar) 33% social class III$_2$ (blue collar) 10% social class IV & V (lower classes) and 7% students The social class scale is an adaptation of the British Registrar Generals Occupational Rating (5)

Babies of families living in Kiryat Hayovel and born between June 1st 1971 and December 31st 1973 have been included in this study 9 % of those living in the area at 9 months were examined and blood samples collected (n=858) at the neighbourhood health center of the Hadassah-Hebrew University Department of Social Medicine

The study of weight and length was confined to those born between June 1st 1971 and May 31st 1972 (n=465) Low birth weight babies were excluded from the analysis

METHODS

The babies were examined between 9 and 10 months of age the clinical and developmental examination being performed by a physician and anthropometry by specially trained nurses with standard equipment (3) Stuart s weight and length percentiles were interpolated into 5 percentile categories for weekly age intervals by sex On the

AN EPIDEMIOLOGICAL STUDY OF HAEMOGLOBIN LEVELS IN INFANCY IN JERUSALEM

The Effect of Social Factors and the Relation to Physical Growth

H PALTI B ADLER and N WOLF

From the Department of Social Medicine The Hebrew University Hadassah Medical School Jerusalem Israel

ABSTRACT Palti H Adler B and Wolf N (Department of Social Medicine the Hebrew University Hadassah Medical School Jerusalem Israel) An epidemiological study of haemoglobin levels in infancy in Jerusalem The effect of social factors and the relation to physical growth Acta Paediatr Scand 66 513 1977 —The infant population of a mixed middle and low social class community in a western neighbourhood of Jerusalem has been examined for haemoglobin haematocrit weight and length at 9 months of age The mean haemoglobin has been 11 1 g/100 ml the mean haematocrit 36 1 and the mean MCHC 31 1% In most cases the anemia has been mild Statistically significant differences in the mean haemoglobin have been found by social class of father and sex of the child No statistically significant association has been found between birth weight weight and length at 9 months and mean weight increment per week between birth and 9 months of age and haemoglobin Lower levels of Hb have been demonstrated in the males by categories of birth weight and categories of weight increment

KEY WORDS Haemoglobin social factors physical growth sex

Anemia due to iron deficiency has been shown to be prevalent in early childhood in Israel (6 8 12)

A surveillance program of the physical and psychomotor development of 0–5 year old children has been established in a neighbourhood of Jerusalem (4) All babies of the community have also haemoglobin and haematocrit examinations carried out at 9 months of age The aim of this being to obtain information about the distribution of haemoglobin and to screen for anemia needing treatment

The haematological and growth data allow for study of the correlation between haemoglobin and physical growth

MATERIAL

rank and sex of child on the haemoglobin level as calculated by analysis of variance is shown in Table 1

The mean haemoglobin level of males was 10 96 g/100 ml and than that of females 11 30 g/100 ml ($p=0\ 001$)

The difference in haemoglobin by social class of father was also found to be significant ($p=0\ 014$) Children born to fathers from social class I+II had the highest mean level of haemoglobin 11 44 g/100 ml No significant differences were found in mean haemoglobin by region of birth or education of mother and by birth rank

The five variables included in the analysis explain 6% of the variance

(c) *Relation between physical measurements and haemoglobin*

Birth weight The mean birthweight for males was 3 330 g S D 406 g and for females 3 240 g S D 317 The difference in birthweight by sex was statistically significant ($p=0\ 002$) Lower mean haemoglobin are noticed in the 2 501–3 000 g birth weight group than in the other groups This difference is not statistically significant neither for males nor for females (Table 2)

The haemoglobin level of males was consistently lower than that of females the difference being statistically significant when analysed according to birth weight categories ($p<0\ 001$)

The percentile for weight and length at 9 months of age was calculated for each sex separately No statistically significant differences were found in the mean haemoglobin by the percentile of weight or length at 9 month of age in the group as a whole and in each sex separately The difference in haemoglobin was statistically not significant by length

Mean increment in weight per week was calculated Those who had a mean increment of 130–150 g/week had the highest mean haemoglobin at 9 month of age both males and females The differences between the categories of increment in each sex separately and in the total population were not significant but in the categories of weight increments the difference between the sexes was significant ($p<0\ 003$) (Table 3)

DISCUSSION

The present study provides information about the infant population of a mixed middle and lower social class community in a western neighbourhood of Jerusalem at the age of 9 months The mean haemoglobin of 11 1 g/100 ml found in this population is somewhat lower than that found by Burman in Bristol (2) at the same age or by Samuelson (9) in North Sweden at 1 year of age

The distribution of the haemoglobin indi

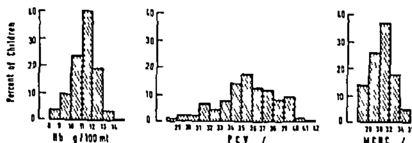

Fig 1 Distribution of Hb PCV and MCHC of 9 month old infants (n=858)

basis of these tables weight and length measurements were translated into percentiles by computor Weight increment was calculated from birth to the date of measurement and from it the average increment per week was computed

Haemoglobin and haematocrit determinations were done by special appointment none during acute febrile illnesses Capillary blood samples were taken from finger prick without compression of the finger Haemoglobin concentration was determined as cyanmethaemoglobin Interobserver variation was checked in 135 cases by two independent observers doing the determination twice on the same blood sample The mean of the difference was 0 11 g/100 ml The error as calculated by Samuelson (9) was found to be $\pm$0 27 g/100 ml

Packed cell volume was determined with a microhaematocrit centerifuge

Statistical analysis Means and standard deviations for haemoglobin and haematocrit were calculated The effect of 5 factors namely sex birth rank social class mothers educational standard and region of origin was determined by analysis of variance (10) The effect of one factor on the haemoglobin was calculated while controlling for the other variables included in the analysis The percent of the explained variance due to the above mentioned variables was calculated

The one way analysis of variance was used to study the effect of growth on the haemoglobin in each sex separately To study the sex differences in haemoglobin while controlling for the growth variable the Z test was used Both techniques were used in Tables 2 and 3

RESULTS

(*a*) *Haematological results*

The distribution of haemoglobin PCV and MCHC for the whole community of children is presented in Fig 1

Haemoglobin The mean haemoglobin is 11 1 g/100 ml S D 1 2 (n=858) A haemoglobin level below 9 g/100 ml was found in 3 8% of children below 10 g/100 ml in 13 5% and below 11 g/100 ml in 37 3%

Packed cell volume The mean PCV is 36 1 S D 2 8 (n=845) A haematocrit level below 34 was found in 16 8% of children

Mean corpuscular haemoglobin concentration The mean MCHC was 31 1% S D 2 5 An MCHC less than 31 was found in 40% of children

(*b*) *Effect of sociocultural background on the haemoglobin level*

The separate effect of social class of father education and region of origin of mother birth

cates that the prevalence of a level below 11 g/100 ml ıs 37%, but only 13 5% of these fall below 10 g/100 ml Therefore most of the ınfants consıdered anemıc by the WHO definıtıon of anemıa 11 g/100 ml (11) have a mıld anemıa The PCV determınatıon and the calculatıon of the MCHC ındıcate that the anemıa ıs most probably due to ıron deficıency Iron deficıency was shown as the maın cause of anemıa ın ınfancy and early chıldhood ın Israelı chıldren from an ımmıgrant town settlement (6) Low ıron ıntakes durıng the first year of lıfe have been demonstrated ın a sample of chıldren ın our communıty (7)

The hıgher prevalence of anemıa ın thıs study ın comparıson to those from Brıstol or North Sweden may be due to dıfferences ın the socıoeconomıc factors of the populatıons The communıty presented here ıs maınly socıal class III and below A statıstıcally sıgnıficant dıfference ın the haemoglobın level was shown by socıal class The mean haemoglobın was lower ın the lower socıal class groups

No effect of the bırth rank on the haemoglobın level was noted In the populatıon studıed anemıa of pregnancy ıs ıntensıvely treated (8) Maıntenance of normal levels of haemoglobın durıng pregnancy may have amelıorated the effect of successıve bırth on the development of anemıa ın ınfancy

No assocıatıon between bırth weıght and length and mean weıght ıncrement per week and haemoglobın level at nıne month of age could be shown for each sex separately Burman (2) demonstrated the effect of bırth weıght on haemoglobın up tıll the age of three month but none ın the later age groups It was postulated by Beal (1) that ınfants wıth hıgh ıncrements have ıncreased appetıtes and theır ıron ıntake per kg ıs the same as that of ınfant wıth lower ıncrements

The sex dıfferences ın haemoglobın level were hıghly sıgnıficant Are these dıfferences due to dıfferences ın growth? Bırth weıght was hıgher ın males than ın females ($p<0\ 003$) The analysıs of the mean haemoglobın by bırth weıght ındıcated that ın each sex the dıfferences are not sıgnıficant, but ın the categorıes of bırth weıght males have persıstently lower mean haemoglobın than females In addıtıon whıle studyıng mean weıght ıncrement per week from bırth to nıne month males have lower mean haemoglobın levels ın the same categorıes of weıght ıncrement than females thıs dıfference ıs of hıgh statıstıcal sıgnıficance The conclusıon from these findıngs are that the dıfferences ın haemoblobın level by sex are not related to growth Investıgatıon of susceptıbılıty to ınfectıon by sex and ıts relatıonshıp to anemıa mıght throw further lıght on the above mentıoned sex dıfferences

The five varıables studıed explaın only 6% of the varıance therefore further factors have to be studıed lıke ıron ıntake sources of ıron ın the dıet blood loss and the common ıllnesses of ınfancy lıke dıarrheal and upper respıratory dıseases

ACKNOWLEDGEMENT

We thank Prof S L Kark Head of the Department of Socıal Medıcıne of the Hebrew Unıversıty Hadassah Medıcal School and Chaırman of the program of development for hıs support and advıce Dr Z Shamır Head of the Mother and Chıld Health unıt and the staff from Kıryat Hayovel Communıty Health Center of the Department of Socıal Medıcıne who took part ın the surveıllance

CASE REPORT

FAILURE OF DETERMINATION OF FETAL LUNG MATURATION DUE TO FALSE NEGATIVE LECITHIN/SPHINGOMYELIN RATIO IN A CASE OF PIERRE ROBIN SYNDROME

D PELEG J GOLDMAN J BOYANOVER and E ELIAN

From the Department of Obstetrics and Gynecology and Department of Pediatrics Hasharon Hospital Petah Tikva and Tel Aviv University Medical School Tel Aviv Israel

ABSTRACT Peleg D Goldman J Boyanover J and Elian E (Department of Obstetrics-Gynecology and Department of Pediatrics Hasharon Hospital Petah Tikva and Tel Aviv University Medical School Tel Aviv Israel) Failure of determination of fetal lung maturation due to false negative lecithin/sphingomyelin ratio in a case of Pierre Robin syndrome Acta Paediatr Scand 66 519 1977 —A case is reported of a baby with Pierre Robin syndrome born at term with adequate lung maturity The evaluation of fetal lung maturity before birth by means of the lecithin/sphingomyelin ratio and foam test in the amniotic fluid revealed immaturity of the lungs Examination of the tracheal aspirate following delivery however showed adequate lung maturity in the neonate

KEY WORDS L/S ratio foam test lung maturity amniotic fluid tracheal aspirate Pierre Robin syndrome

Several methods have been suggested for the evaluation of fetal lung maturity by means of the amniotic fluid One of the well accepted methods is he determination of lecithin/sphingomyelin (L/S) ratio (5) Since this test requires specialized manpower and equipment simpler tests such as the rapid foam or bubble test have been used This test is also rather reliable (4) Recently both the tracheal aspirate and gastric fluid in the newborn baby have been found to be well suited for the determination of both these tests (1 2 7) As shown by Giudicelli et al (6) most of the phospholipids present in tracheal aspirate and amniotic gluid are identical in proportion and fatty acid composition

Nevertheless in spite of the reliability of the foam test and the L/S ratio in the amniotic fluid in certain conditions they are unreliable The doubtful cases include staining of the fluid by blood or meconium in diabetes mellitus of the mother complicating pregnancy (3) and in other conditions Moreover little has been said in the literature on the subject of congenital malformations which do not permit the determination of lung maturity in the amniotic fluid as for example may be demonstrated in the syndrome of Pierre Robin This type of anomaly may be concerned with the impeded passage of lecithins from the fetal lungs into the amniotic fluid most probably due to hyperextension of the baby s head and prolapse of the tongue

CASE REPORT

A 23 year-old woman with normal pregnancy and delivery in the past was admitted to the delivery floor of Sharon Hospital in the 40th week of her second pregnancy On examination mild preeclamptic toxemia and suspected breech presentation X ray examination confirmed the breech position with marked extension of the head In view of this finding amniocentesis with fetography was performed by means of Pantopaque (ethyl iodophenylundecanoate) and Lipiodol (sodium diatrizoate meglumine diatrizoate) The latter failed to reveal evidence of a cervical tumor as a cause for hyperextension or other external fetal abnormalities Repeat X rays 12 and 24 hours after amniocentesis and injection of the contrast material proved the lack of swallowed opaque fluid by the fetus Foam test performed as a routine test for the determination of fetal lung maturity was negative in all dilutions while the L/S ratio was 1 0

CASE REPORT

A 23 year-old woman with normal pregnancy and delivery in the past was admitted to the delivery floor of Sharon Hospital in the 40th week of her second pregnancy On examination mild preeclamptic toxemia and suspected breech presentation X ray examination confirmed the breech position with marked extension of the head In view of this finding amniocentesis with fetography was performed by means of Pantopaque (ethyl iodophenylundecanoate) and Lipiodol (sodium diatrizoate meglumine diatrizoate) The latter failed to reveal evidence of a cervical tumor as a cause for hyperextension or other external fetal abnormalities Repeat X rays 1? and ?4 hours after amniocentesis and injection of the contrast material proved the lack of swallowed opaque fluid by the fetus Foam test performed as a routine test for the determination of fetal lung maturity was negative in all dilutions while the L/S ratio was 1 0

The L/S ratio was determined as follows After extraction in a mixture of chloroform and methanol and precipitation in acetone phospholipids were separated on silica gel G plates The separated sphingomyelin and lecithin were collected from the plates their ratio being determined by the phosphate ratio determination The method is based on the reaction between phospho ammoniummolybdate and α aminonaphtosulfonic acid reagent Creatinine and uric aicd levels showed good fetal maturity

Following admission uterine concentrations started however in view of the fetal presentation Caesarean section was performed When the uterine cavity was opened an exceptionally large amount of clear amniotic fluid was found The fetus was seen to be in breech presentation with marked hyperextension of the head and the umbilical cord twice around the baby s neck The baby was delivered in satisfactory condition with Apgar score of 8 after 1 min and 9 after 5 min Immediately following delivery the fluid from the trachea and pharynx were sucked by means of a mucus extractor the foam test was done in this aspirate and found to be positive in all dilutions The L/S ratio was 3 2 Physical examination of the neonate revealed the typical triad including gueule de loup and micrognatia corresponding to the Pierre Robin syndrome The baby remained with a hyperextended head for several days showing no signs of repsiratory distress

COMMENT

A newborn with Pierre Robin syndrome has been described in whom the connection between the fetal lungs and the amniotic fluid in the uterine cavity was obstructed possibly due to prolapse of the tongue The intrauterine obstruction of the linkage between the fetal laryngopharynx and the amniotic fluid may be evidenced by hydramnion and the faulty swallowing of contrast material during fetography Furthermore, it is probable that this obstruction resulted in failure of the foam test and L/S ratio in the amniotic fluid to demonstrate fetal lung maturity In fact this block between the respiratory system of the fetus and the amniotic cavity may have resulted in the reduction of lecithins in the amniotic fluid Nevertheless when the baby was delivered the true lung maturity of the infant could be determined in the trecheal aspirate by means of the mentioned tests indeed good lung maturity was found in the baby

This case stresses the significance of the determination of fetal lung maturity as evaluated by means of the foam test and L/S ratio in the tracheal aspirate This determination offers the present and true lung maturity independently of the free flow between fetal lungs and its environment

It is possible that in other malformations of the laryngopharynx a similar failure of evaluation of lung maturity in the amniotic fluid may be found Consequently attention is drawn to the fact that in case of negative L/S ratio in the amniotic fluid in term pregnancy other than a false negative test a fetal anomaly should be suspected, blocking the exchange between the fetal lungs and the amniotic cavity

CASE REPORT

ECHOCARDIOGRAPHIC DIAGNOSIS OF AN ANEURYSM OF THE MEMBRANOUS VENTRICULAR SEPTUM

J H FAST and R J MOENE

From the Department of Cardiology Free University Hospital Amsterdam The Netherlands

ABSTRACT Fast J H and Moene R J (Department of Cardiology Free University Hospital Amsterdam The Netherlands) Echocardiographic diagnosis of an aneurysm of the membranous ventricular septum Acta Paediatr Scand 66 521 1977 —A patient with a small ventricular septal defect complicated by an aneurysm of the membranous ventricular septum is reported The aneurysm was diagnosed by left ventricular angiocardiography and non invasively by echocardiography The clinical significance of the anomaly is discussed in relation to the pertinent literature

KEY WORDS Aneurysm of the membranous ventricular septum echocardiography

Aneurysm of the membranous portion of the ventricular septum although an unusual lesion should be recognized in an early stage since it may accompany spontaneous diminution in the size of an associated membranous ventricular septal defect and in some cases may be a prelude to spontaneous closure of ventricular septal defects (9 12) Until recently selective angiocardiography was the only reliable (non surgical) means of diagnosing the anomaly during life as there are no specific diagnostic findings on physical examination electrocardiography or radiography

This report emphasizes the value of echocardiography as a non invasive means of diagnosing this lesion

CASE REPORT

The patient a boy was born on April 10 1973 after a full term uneventful pregnancy At the age of 3 months he was admitted to the hospital because of tachypnoea and the discovery of a heart murmur

Physical examination revealed a dyspnoeic infant with signs of congestive heart failure the heart was enlarged and the liver was palpable 3 cm below the costal margin Auscultation disclosed a grade 3/6 pansystolic murmur maximal at the left of the sternal border a second heart sound of normal intensity and a third heart sound at the apex The electrocardiogram showed left ventricular hypertrophy the chest X ray revealed a slight prominence of the pulmonary vascular markings and a slightly enlarged heart

The diagnosis of ventricular septal defect was made and heart failure was successfully treated by digitalis

The boy grew without problems and at the age of one year digitalis was discontinued

At the age of 3 years the child was asymptomatic at that time physical examination revealed a grade 3/6 pansystolic murmur without signs of heart failure The electrocardiogram and the chest X ray were normalized Cardiac catheterization demonstrated a small left to-right shunt at the ventricular level with normal cardiac pressures the pulmonary to systemic flow ratio was 1 5 1 A ciné angiocardiogram of the left ventricle showed an aneurysm of the membranous septum with a minimal left to-right shunt (Fig 1)

Using an ECHO cardiovisor with multiscan facilities and placing the transducer in a sagittal LV long axis cross section position the aneurysm was visualized as a mass of echoes protruding in the outflow tract of the right ventricle during the systolic phase of the heart cycle During diastole the aneurysmal bulge was completely absent From the moving picture a single frame taken during systole is reproduced in Fig 2

No operative treatment was recommended but close follow up observation will be carried out

The L/S ratio was determined as follows After extraction in a mixture of chloroform and methanol and precipitation in acetone phospholipids were separated on silica gel G plates The separated sphingomyelin and lecithin were collected from the plates their ratio being determined by the phosphate ratio determination The method is based on the reaction between phospho ammoniummolybdate and α aminonaphtosulfonic acid reagent Creatinine and uric aicd levels showed good fetal maturity

Following admission uterine concentrations started however in view of the fetal presentation Caesarean section was performed When the uterine cavity was opened an exceptionally large amount of clear amniotic fluid was found The fetus was seen to be in breech presentation with marked hyperextension of the head and the umbilical cord twice around the baby s neck The baby was delivered in satisfactory condition with Apgar score of 8 after 1 min and 9 after 5 min Immediately following delivery the fluid from the trachea and pharynx were sucked by means of a mucus extractor the foam test was done in this aspirate and found to be positive in all dilutions The L/S ratio was 3 2 Physical examination of the neonate revealed the typical triad including gueule de loup and micrognatia corresponding to the Pierre Robin syndrome The baby remained with a hyperextended head for several days showing no signs of repsiratory distress

DISCUSSION

Lev & Saphir (7) attributed the first description of an aneurysm of the ventricular septum to Laennec in 1826 Since the first ante mortem diagnosis by Steinberg in 1957 (11) several cases have been diagnosed by surgery or angiocardiography The incidence of aneurysm of the ventricular septum found at autopsy has been reported to be low (8 11) Varghese et al (12) however reviewed forty eight left ventricular cine angiocardiograms of patients with ventricular septal defects investigated over a 2 year period and found 16 aneurysms of the membranous septum The majority of aneurysms occurred in the presence of a small ventricular septal defect A high incidence was recently also reported by Freedom et al (4)

Mall postulated a congenital origin of these aneurysms and several other authors accepted the concept of a congenital origin (4)

This hypothesis is not supported by recent reports (6 12) in which aneurysm formation is ascribed to or described to occur in association with spontaneous closure of ventricular septal defects Spontaneous closure of muscular defects may occur by apposition of the margins of the defect (13) Many membranous defects also close spontaneously the mechanisms are not yet definitely understood however The only documented mode of closure of these defects is adherence of the medial leaflet of the tricuspid valve to the margins of the defect (2) In addition there is some evidence that endocardial proliferation stimulated by turbulent blood flow through the defect, may cause closure of a membranous defect (13) The weakness of this newly formed tissue may cause it to bulge into the right ventricular cavity as a result of the higher left ventricular pressure (10) Varghese et al (12) reported a proved case of aneurysm of the membranous septum with a ventricular septal defect which later closed spontaneously

This observation together with the frequent association of aneurysms with small ventricular defects strongly suggests that aneurysmal formation may be a prelude to spontaneous closure of these defects

The patient presented here was in congestive heart failure at the age of 3 months at the age of 3 years he was asymptomatic and the electrocardiogram and the chest X ray were normalized suggesting a diminution of the size of the defect In this regard the demonstration of a septal aneurysm in patients with a ventricular septal defect is an additional sign of reduced defect size According to some authors (4 5) certain phonocardiographic features are most suggestive of an aneurysm with associated septal defect i e an early systolic click and late systolic accentuation of the VSD murmur In our patient these signs were absent and the aneurysm was demonstrated by left ventricular angiocardiography

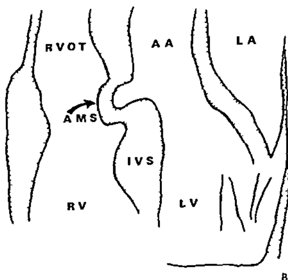

Fig 2 (A) Echocardiographic picture of the aneurysms of the membranous septum (B) Schematic drawing of the echocardiographic picture *A A* =ascending aorta *A M S* =aneurysm of the membranous septum *I V S* = interventricular septum *L A* =left atrium *L V* =left ventricle *R V* =right ventricle *R V O T* =right ventricular outflow tract

Real time two dimensional ultrasonic cardiac visaging permits a non invasive accurate study of the complete movement of the interventricular septum In this patient a mass of echoes was noted near the base of the septum at the place of the aneurysm

The documentation given in the present report (Fig 2) is still more convincing when viewing the moving picture Assad Morell et al (1) used the single element echocardiographic technique to demonstrate the presence of an aneurysm of the membranous septum This technique gives pictures of a higher quality than the two-dimensional technique because of the poor resolution in the presently available real time two-dimensional picture However when viewing the two-dimensional picture in real time the important information of motion in the picture is added

Since rupture endocarditis thromboembolism obstruction of the right ventricular outflow aortic insufficiency and conduction disturbances have been documented as complications of septal aneurysms (10) a long term follow up of these patients is needed to evaluate the natural course of this anomaly In this respect echocardiography is an elegant tool for the assessing of the presence and the dimension of septal aneurysms

CASE REPORT

T3 TOXICOSIS IN CHILDREN

P C HARLAND R G McARTHUR and D M FAWCETT

From the Division of Paediatrics Faculty of Medicine University of Calgary Calgary Canada

ABSTRACT Harland P C McArthur R G and Fawcett D M (Division of Paediatrics Faculty of Medicine University of Calgary Calgary Alberta) T3 toxicosis in children Acta Paediatr Scand 66 525 1977.—Triiodothyronine (T3) toxicity has been well documented in adults but only isolated cases have been reported in children Two girls presented with firm goitres and overt hyperthyroidism In each patient total serum thyroxine (T4) values by competitive protein binding were normal however total T3 values by radioimmunoassay were elevated One patient had Graves disease the second patient had Hashimoto s disease which has been only infrequently associated with T3 toxicity in adults Both patients responded to therapy with propylthiouracil The mechanisms by which T3 is preferentially secreted in thyrotoxic states in man are poorly understood but iodine deficiency and poor iodination of thyroglobulin may be important factors

KEY WORDS Children T3 thyrotoxicosis Hashimoto s disease

The recent development of a simple and rapid immunoassay for triiodothyronine (T3) in serum (7 8 9) has opened interest in the contribution of this hormone in thyrotoxic states T3 toxicity in the presence of normal serum thyroxine (T4) has been well documented in adults (13 15 25) In the paediatric literature however only isolated cases have been reported (17 22) suggesting that this disorder may be less frequent in childhood

Two children are reported who demonstrated an elevation in T3 Each was referred as a diagnostic problem in that their clinical findings suggested thyrotoxicosis but the usual thyroid function tests were normal

METHODS

Total serum T4 was measured by the Ames tetralute method (University of Alberta Edmonton) and by competitive protein binding analysis (Bio-Science Laboratories Van Nuys California)

Serum free T4 was measured with the aid of magnesium precipitation and radioimmunoassay (Bio Science Laboratories Van Nuys California)

Total serum T3 was measured by radioimmunoassay (Bio-Science Laboratories Van Nuys California)

Antithyroglobulin antibody titres and thyroid binding globulin (T B G) were measured by Bio Science Laboratories Van Nuys California [131]I uptakes were determined by standard methods

REPORT OF CASES

Patient 1 This 10 year-old girl was found to be thyrotoxic during hospital admission for infectious hepatitis For 6 months prior to admission she had noticed heat intolerance emotional lability sweaty palms and palpitations Examination revealed a pulse of 110 *per minute fine tremor of the hands* overt exophthalmos and an enlarged firm irregular thyroid twice normal size weighing approximately 50 g The blood pressure was 115/60 There was no family history of thyroid disease

Investigations (Table 1) showed a normal T4 (6 4 µg/100 ml) elevated T3 (266 ng/100 ml) and a high [131]I uptake (71% at 4 hours) Antithyroglobulin antibodies were present in a titre of 1 2 500 and the T B G was normal (15 µg/100 ml) Typical *Hashimoto* s disease was later reported on thyroid biopsy

Table 1 *Thyroid function in 2 children with T3 toxicosis*

Test	T4 by C P B µg/100 ml	Free T4 (ng/100 ml)	T3 by R I A (ng/100 ml)	¹³¹I uptake (%)	Thyroid antibody titre	T B G (µg T4/100 ml)	Biopsy
Normal	3 0–7 0	2 7–5 7	60–190	4 hrs 5–15 24 hrs 10–35	<1 16	10–26	
Pt I	6 4	7 4	266	4 hrs 21 24 hrs 36	1 2 500	15	Hashimoto s
Pt II	6 2	6 3	372	4 hrs 17 24 hrs 33	1 32	20	Graves

She was treated with propylthiouracil 50 mg q 8 h for 2 years Two months following the initiation of therapy symptoms had improved and the serum T3 value was normal (112 ng/100 ml) One year after the discontinuation of propylthiouracil she remains well with a normal serum T3 level

Patient II This girl aged 10 years gave a 1 year history of increasing restlessness tremor of the hands emotional lability and enlargement of the thyroid Her mother had 2 operations for Graves disease at age 9 and 10 years Examination revealed an anxious fidgety girl with mild exophthalmos and a pulse of 110/minute The thyroid gland was firm diffusely enlarged and felt 3 times normal size weighing approximately 75 g The blood pressure was 115/60

Thyroid studies (Table 1) showed a normal T4 (6 2 µg/100 ml) The free T4 was marginally elevated (6 3 ng/100 ml) and the total T3 was elevated at 372 ng/100 ml Antithyroglobulin antibodies were present in a titre of 1 32 and T B G was normal (20 µg/100 ml) Thyroid biopsy showed histology compatible with Graves disease

She was initially treated with propylthiouracil 100 mg every 8 hours for 2 months She was subsequently maintained on 75 mg every 8 hours for 2 years Two months following the initiation of therapy she appeared euthyroid and her serum T3 level was 146 ng/100 ml Six months after the discontinuation of propylthiuracil therapy she remains well with a normal serum T3 level

DISCUSSION

We believe that our patients exhibited true T3 toxicosis although we recognize that the T3 levels in our subjects are not as high as may be found in adults with T3 toxicosis (13 15 25) and that normal values for serum T3 are higher in children than adults (23) In one reported paediatric case the T3 level was 1 200 ng/ml (17) The free T4 values though above the normal range in our 2 patients are not as high as levels usually seen in T4 thyrotoxic children Also elevated were the radioactive iodine uptake levels at 4 and 24 hours This is consistent with adult reports of T3 toxicity Normal binding of T4 was confirmed by normal T B G levels The biopsy results showed that one patient had Hashimoto s disease which has been only infrequently associated with T3 toxicosis in adults The other girl with lower antibody titres had Graves disease confirming reports (2, 16) that antibodies may be found in this disease

The circulating pool of T3 in man is derived from 2 sources (Fig 1) 1) the thyroid gland and 2) the peripheral conversion of T4 to T3 (4 10 11 21 24) T3 in euthyroid subjects is secreted in smaller quantities than thyroxine, however its significance is heightened by its greater calorigenic effect estimated to be 3 to 4 times more potent than T4 (19 18)

The advent of radioimmunoassay in measuring serum T3 and T4 has delineated the entity of T3 toxicosis accurately and allowed investigators to evaluate its importance in thyroid disease There appears to be a wide biochemical spectrum in the ability of the hyperactive thyroid gland to secrete variable quantities of either hormone and those patients in which T3 alone is elevated represent a variation in the spectrum

Both T4 and T3 are normally synthesized at the same rate (10) T3 is formed by the coupling of monoiodotyrosine (MIT) to diiodotyrosine (DIT) and T4 by the coupling of 2 DIT residues It would be logical that the formation of T3 and T4 depend upon the relative availability of MIT and DIT

Data from animal studies indicate that the normal thyroid increases secretion of T3 rela

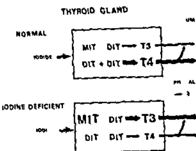

Fig 1 Variations in production of T3 in normal and iodine deficient subjects

tive to T4 during iodine deficiency Rats fed a low iodine diet increase the MIT/DIT ratio in newly formed thyroglobulin within 24 hours (26) such that within 2 weeks the T3/T4 ratio has also increased That similar factors (Fig 1) predispose to preferential secretion of T3 in man is supported by the high incidence of T3 toxicity in iodine deficient areas (14 20)

It is therefore attractive to consider that relatively poor iodination of thyroglobulin occurred in our patients resulting in preferential secretion of the more potent T3 This has been readily demonstrated in patients following thyroid irradiation where there is a relative block in organic binding of iodine and a decrease in overall iodine accumulation (3) Similar abnormalities in intrathyroidal iodine have been demonstrated in Hashimoto s disease (27 5) Elevated T3 levels in Graves disease may be explained on the basis that high serum iodine inhibits intrathyroidal organification of iodine and blocks release of T4 (12)

T3 in the serum may also be derived from non thyroidal sources Evidence suggests that in normal (24) or hypothyroid (4) patients exogenous T4 is converted to T3 Chopra (6) recently estimated that 3/4 of circulating T3 arises from the peripheral conversion of T4 to T3 This again raises the question whether T4 is primarily active or exerts its metabolic effect only after deiodination to T3

The incidence of T3 thyrotoxicosis in adults has been estimated at 5–10% (14 1) of all thyrotoxic patients In iodine deficient areas this is much higher (14 20) Too little information is presently available to determine the true incidence of T3 toxicosis in children

In summary two thyrotoxic children were investigated In each total serum T4 and thyroxine binding globulin were normal while total serum T3 levels were elevated Our cases demonstrate that T3 toxicosis must be suspected when the patient appears thyrotoxic but routine thyroid function tests fail to support the clinical diagnosis

ACKNOWLEDGEMENTS

CARBAMYL PHOSPHATE SYNTHETASE DEFICIENCY WITH NEONATAL ONSET OF SYMPTOMS

J P FARRIAUX Cl PONTE[2] R J POLLITT[3] P LEQUIEN[2] P FORMSTECHER and J L DHONDT[1]

From the Service de Genetique et Maladies Hereditaires du Metabolisme de l'Enfant Cite Hospitaliere and the [2]Service de Pediatrie I athologie du premier age Hopital A Calmette Lille France and [3]M R C Unit for Metal olic Studies in Psychiatry Middlewood Hospital Sheffield UK

ABSTRACT Farriaux J P Ponte Cl Pollitt R J Lequien P Formstecher P and Dhondt J L (Service de Genetique et Maladies Hereditaires du Metabolisme de l Enfant Cite Hospitaliere Lille Hopital Calmette Lille France and M R C Unit for Metabolic Studies in Psychiatry Sheffield UK) Carbamyl phosphate synthetase deficiency with neonatal onset of symptoms Acta Paediatr Scand 66 529 1977 —The clinical course and biochemical findings in a case of carbamyl phosphate-synthetase deficiency are described The patient a boy presented 48 h after birth with rapidly developing hypotonia and hypothermia Pulmonary haemorrhage melaena and haematemesis ensued and despite ventilatory assistance and peritoneal dialysis the patient died on the fifth day A virtual absence of carbamyl phosphate synthetase I (N acetylglutamate dependent) was proved by analysis of tissue samples removed post mortem Other urea cycle enzymes were normal

KEY WORDS Urea cycle hyperammonaemia

Carbamyl phosphate synthetase (CPS) deficiency is one of the more recently described (12) of the hereditary anomalies of the urea cycle enzymes It is also one of the least common (8 cases) particularly as among the observations presented as CPS deficiency some appear debatable including the original case described by Freeman et al (12) Significantly decreased levels of hepatic CPS can be encountered in other conditions—Reye s syndrome (29) non ketotic hyperglycinaemia (22) hyperornithinaemia with hyperammonaemia and homocitrullinuria (13) methylmalonic acidaemia (18 20) and propionic acidaemia (6) We have borne this point in mind in the investigation of the present case the second to be reported in detail

CASE REPORT

The patient was the second child of young (25 and 26 y) healthy non-consanguinous parents with no family history of illness Their first child a girl was born in 197- and had been healthy except for an isolated and unexplained convulsive episode in 1975 The patient a boy (R J) was born at term after an uneventful pregnancy and confinement He weighed 3 700 g was 52 cm long and had Apgar scores of 10 at 1 and at 5 min For the first 48 h of life he presented no problems but then became fretful hypotonic and hypothermic He was transferred to the neonatal intensive care unit where on admission at 56 h of age he was found to be drowsy and hypotonic with loss of primitive reflexes Despite intravenous administration of 10% glucose solution and antibiotics and feeding by gavage with donated human milk and Lacmil (8×20 ml) the patient s condition progressively worsened and irregular laboured breathing developed Ventilatory assistance was started at 66 h The child remained hypotonic with hyperactive tendon reflexes and his general condition deteriorated until by 78 h he was cyanosed and grey The pharyngeal aspirate contained fresh blood and there was haematemesis and melaena All alimentation was then withdrawn and peritoneal dialysis begun with 17 cycles of 100 ml between the 78th and 93rd hours This had no clinical effect and the child s condition remained unchanged until death in the 104th hour of life

LABORATORY METHODS

Plasma ammonia was determined by Berthelot s method using the Hyland blood ammonia test kit Blood amino

Table 3 *Carbamyl phosphate synthetase activity (μmol/h/g tissue) in post mortem tissue specimens (R J) (^{14}C method)*

The results in brackets were obtained with the addition of OCT in the form of a homogenate of the patient s liver correcting for residual CPS activity

	With *N* acetyl glutamate	Without *N* acetyl glutamate
Liver	0 140	0 090
Intestine	0 0 0 (0 0 6)	0 070
Brain	<0 001 (0 002)	<0 001
Kidney	0 070 (0 078)	0 070
Control (rat liver)	49 7	1 45

9–44 μmol/l) 1488 μmol/l at 78 h and 1048 μmol/l after peritoneal dialysis The plasma amino acid pattern (Table 1) was abnormal with an almost complete absence of citrulline and considerable increases in a number of amino acids The cerebrospinal fluid also showed a highly abnormal amino acid composition (Table 1) There was a normal urinary excretion of orotic acid (0 16 mg/ml equal to 0 20 mg/mg creatinine) and no abnormal increase in argininosuccinic propionic methylmalonic or isovaleric acid excretion

Enzyme analysis on tissues removed within minutes of death showed a virtual absence of CPS with normal levels of the other urea cycle enzymes (Table 2) The radiochemical determination of CPS (Table 3) permitted the conclusion that the residual activity in liver about 0 25% of normal was due largely to CPS II (Cytoplasmic CPS—glutamine dependent) as activity was only slightly reduced on omission of *N* acetylglutamate from the incubation mixture Cultured skin fibroblasts from the patient gave CPS activities (with addition of liver homogenate) of 0 005 and 0 007 μmol/h/g of packed cells with and without *N* acetylglutamate respectively A single control sample gave 0 001 μmol/h/g in each case The CPS I activity of these fibroblasts was thus extremely low or zero

The blood urea level was low at 2 mmol/l (0 12 g/l) The serum showed raised levels of enzymes—glutamate oxaloacetate transaminase 145 I U (normal <40), lactate dehydrogenase 600 I U (normal <200) and alkaline phosphatase 117 I U (normal <70) Other investigations showed a lowering of coagulation factors (VII+X V and VIII) to between 34 and 50% of normal and in the E E G signs of severe irritation with epileptic discharges on both left and right

The patient s parents showed normal blood ammonia and amino acid levels and normal urinary amino acids and orotic acid both before and after the ammonium chloride load

DISCUSSION

Clinically two main types of inherited CPS deficiency seem to be distinguishable (Table 4) Firstly there is the neonatal form with a virtual absence of CPS I and characterized by a rapidly fatal outcome with very marked hyperammonaemia (above 500 μmol/l) Four cases of this variant are now known (14 23[1] 27 and the present case) The second variant the slow form carries only a partial deficiency of CPS I with residual activity greater than 10% The survival in these cases is more prolonged with repeated acute episodes and above all a progressive encephalopathy Hyperammonaemia is always more moderate (below 250 μmol/l)

While the first group is clearly defined the second group is more heterogeneous and was divided by Hsia (17) on the basis of cases reported up to 1974 into two sub groups The clinical and biochemical findings are not in themselves particularly specific and a diagnosis of partial CPS deficiency as the primary defect cannot be made until other entities of similar semiology have been excluded Thus in the first reported case of CPS deficiency that of Freeman et al (12) the presence of ketotic acidosis and neutropaenia is

[1] We thank Dr Palmer for sending us unpublished details of this case

[b] Level too low to measure
[c] Insufficient sample for analysis

acids were determined after sulphosalicylic acid deproteinization using ion-exchange chromatography (Beckman Unichrom amino acid analyser) urine and cerebrospinal fluid amino acids were determined similarly without pretreatment of the specimen Urinary orotic acid analysis was by the method of Adachi et al (1) as modified by Rogers & Porter (26) A search for the presence of argininosuccinic acid in the urine was carried out by thin layer chromatography with ninhydrin-cadmium visualization (7) and for propionic methylmalonic and isovaleric acids in urine by gas chromatography (9)

Urea cycle enzymes were determined (*a*) in Lille according to the method of Brown & Cohen (4) as modified by Snodgrass (28) for ornithine carbamyl transferase (OCT) and the colorimetry of citrulline and by Levin et al (21) for the other enzymes (*b*) in the laboratory of Prof Polonovski (by Dr Cathelineau) using the technique previously described (5) and (*c*) in Sheffield by the radioisotopic method of Kerson & Appel (19) after homogenization of the tissues in 0 1% cetyltrimethylammonium bromide

Ammonium chloride tolerance tests on the parents were performed using a single oral dose of 3 g

RESULTS

There was marked hyperammonaemia with levels of 1 537 μmol/l at 71 h of life (normal

both these cases terminated in pulmonary haemorrhage The clinical picture is suffi ciently characteristic that the idea of searching for undiagnosed cases in the family history might be considered On the biochemical side the finding of hyperammonaemia with lowered citrulline but without other specific amino acid abnormalities ketosis or abnormal excretion of organic acids suggested blockage in either of the first two steps of the urea cycle (CPS or OCT) as the primary defect The absence of abnormal excretion of orotic acid indicated CPS deficiency (2 23) This probable diag nosis was confirmed by demonstration of an isolated deficiency of CPS I in liver tissues

The amino acid results merit some discus sion The abnormalities in the plasma amino acids in our patient were similar to those de scribed previously (14) and easily explained in terms of disruption of the urea cycle (raised aspartic acid lowered citrulline) the necessity to detoxify ammonia (raised glutamine) and by hepatic insufficiency (raised tyrosine methionine and alanine) The abnormalities of cerebrospinal fluid amino acids are more dif ficult to interpret It is worth noting however that the glycine levels (107 μmol/l) are in the range quoted by Perry et al (25) for glycine encephalopathy and the CSF/plasma ratio of 0 16 in our patient (normal 0 02) is also in the range quoted for non ketotic hyperglycinae mia (25) In such cases with normal or only moderately raised plasma glycine levels the absence of glycine cleavage enzyme may be evident in the brain but not the liver (22 25)

The treatment of the neonatal form of CPS deficiency is of great urgency but the classical methods of peritoneal dialysis or exchange transfusion are of limited effect The modest decrease in blood ammonia levels produced by peritoneal dialysis in our patient confirms the calculation made by Glasgow & Chase (15) on the efficiency of this method However this method has recently been successful applied to a case of argininosuccinic aciduria (11) and it is quite possible that such emergency meas ures followed up by low protein diet or one based on keto-derivatives of amino acids (3) may be successful in the milder CPS deficiency variants

With regard to the mode of inheritance it is noteworthy that the cases of the lethal ne onatal form were male and female (Table 4) This could support a recessive transmission of CPS but unfortunately no indication of hetero-zygote state could be revealed in the parents (this case and ref 14) Although CPS can be detected in leucocytes (30) our preliminary results seem too untrustworthy for hetero-zygote detection Similarly antenatal diag nosis using fibroblasts may be theoretically possible (Nadler personal communication

ANNOUNCEMENT

There is overwhelming proof that drugs containing 8 hydroxyquinoline derivatives used in treatment of diarrhea may cause serious neurologic damage. The therapeutic benefit from these drugs has not been shown to be in reasonable proportion to the side effects. According to generally accepted medical principles these drugs should for this reason not be used. We appeal to all pharmaceutical companies which are still selling these drugs to discontinue the sale immediately.

BOOK REVIEWS

C R Osborn & N Roydhouse *The tonsillitis habit* T B & W P Roydhouse Publishers Auckland 1976 100 pp illus $12 00

Ever since a Danish surgeon introduced adenoidectomy a hundred years ago this procedure has been met with enthusiasm and its indications have been broad. Unfortunately they still are. This is also true of tonsillectomy. In the foreword to this book Dr Harrison draws attention to the fact that it is only in the last decade that the rationale and the value of the world's most common surgical procedures have been questioned.

The book is an important contribution to the worldwide debate now in progress concerning the indications of these two operations. Certainly part of the material has been previously published but in this monograph extensive experience has been condensed. The book contains clinical findings and practical advice in the conservative management of reversible lesions of the tonsils. One of the authors contributes histopathological views on the reversible and irreversible forms of the tonsillitis habit. One chapter deals with the special anaesthetic problems in this type of oral surgery another with periodontal diseases and their connection with infection in the tonsils. The possible role of cow's milk intolerance and upper respiratory diseases is also discussed. Both the illustrations and the photographs are of high quality. Every chapter has an extensive list of references and there is a name and subject index.

Although the lines upon which to work in regard to T's and A's" remain somewhat unclear even after reading this book and although some of the problems do not apply to all parts of the world—for instance in the Scandinavian countries tonsillectomy in young children and adenotonsillectomy is unusual—the material is certainly of value to every E N T surgeon. Nor is the tonsillitis habit of only minor interest to the paediatrician.

Christer Carenfelt

J A Kuzemko (ed) *Asthma in children* Pitman Medical Publishing Co Ltd London 1976 127 pp illus £3 50 ISBN 0272794007

The prognosis of asthma in children depends on early diagnosis analysis of etiologic factors treatment and careful management. This short text is devoted to children with asthma and covers all aspects of asthma. There is one chapter about the natural history and epidemiology of the disease. One chapter deals with present opinion on the immunology in asthma. There are chapters about history taking and the various allergy tests both in skin and in blood. Tests of pulmonary function are discussed in a special chapter.

Management and treatment are carefully discussed and much good advice and guidance based on deep understanding and practical experience of the disease are given. The chapter on drugs gives a review of the various drugs and their usefulness starting with adrenalin in 1903 and followed by ephedrine in 1925 theophyllamine in 1938 and corticosteroids in 1948. In 1967 we got the selective β receptor stimulants. At the same time sodium cromoglycate was introduced with its good protective effect in children with asthma. Finally we got the steroid aerosols. The effects and side effects of the drugs are carefully discussed.

The book also comprises an up-to-date bibliography of great value. Although it is a slim volume it gives much valuable information for doctors in paediatric practice.

Einar Stenonius

1976) Our results which confirm those of Wolfe et al (30), indicate that the CPS I of fibroblasts is very low and it is difficult at present to envisage the use of fibroblasts for antenatal diagnosis of CPS deficiency

ANNOUNCEMENT

There is overwhelming proof that drugs containing 8 hydroxyquinoline derivatives used in treatment of diarrhea may cause serious neurologic damage The therapeutic benefit from these drugs has not been shown to be in reasonable proportion to the side effects According to generally accepted medical principles these drugs should for this reason not be used We appeal to all pharmaceutical companies which are still selling these drugs to discontinue the sale immediately

BOOK REVIEWS

G R Osborn & N Roydhouse *The tonsillitis habit* T B & W P Roydhouse Publishers Auckland 1976 100 pp illus $17 00

Ever since a Danish surgeon introduced adenoidectomy a hundred years ago this procedure has been met with enthusiasm and its indications have been broad Unfortunately they still are This is also true of tonsillectomy In the foreword to this book Dr Harrison draws attention to the fact that it is only in the last decade that the rationale and the value of the world s most common surgical procedures have been questioned

The book is an important contribution to the worldwide debate now in progress concerning the indications of these two operations Certainly part of the material has been previously published but in this monograph extensive experience has been condensed The book contains clinical findings and practical advice in the conservative management of reversible lesions of the tonsils One of the authors contributes histopathological views on the reversible and irreversible forms of the tonsillitis habit One chapter deals with the special anaesthetic problems in this type of oral surgery another with periodontal diseases and their connection with infection in the tonsils The possible role of cow s milk intolerance and upper respiratory diseases is also discussed Both the illustrations and the photographs are of high quality Every chapter has an extensive list of references and there is a name and subject index

Although the lines upon which to work in regard to T s and A s remain somewhat unclear even after reading this book and although some of the problems do not apply to all parts of the world—for instance in the Scandinavian countries tonsillectomy in young children and adenotonsillectomy is unusual—the material is certainly of value to every E N T surgeon Nor is the tonsillitis habit of only minor interest to the paediatrician

Christer Carenfelt

J A Kuzemko (ed) *Asthma in children* Pitman Medical Publishing Co Ltd London 1976 1?? pp illus £3 50 ISBN 0 272 79400 7

The prognosis of asthma in children depends on early diagnosis analysis of etiologic factors treatment and careful management This short text is devoted to children with asthma and covers all aspects of asthma There is one chapter about the natural history and epidemiology of the disease One chapter deals with present opinion on the immunology in asthma There are chapters about history taking and the various allergy tests both in skin and in blood Tests of pulmonary function are discussed in a special chapter

Management and treatment are carefully discussed and much good advice and guidance based on deep understanding and practical experience of the disease are given The chapter on drugs gives a review of the various drugs and their usefulness starting with adrenalin in 1903 and followed by ephedrine in 19 5 theophyllamine in 1938 and corticosteroids in 1948 In 1967 we got the selective β_2-receptor stimulants At the same time sodium cromoglycate was introduced with its good protective effect in children with asthma Finally we got the steroid aerosols The effects and side effects of the drugs are carefully discussed

The book also comprises an up to-date bibliography of great value Although it is a slim volume it gives much valuable information for doctors in paediatric practice

Ennor Svenonius

D Bergsma & S H Blondheim (eds) *Bilirubin metabolism in the newborn* (II) Birth Defects Original Article Series *Vol XII No 2 Elsevier* Excerpta Medica Amsterdam 1976 348 pp illus US $40 50

This book is a compilation of the papers and discussions held at *The second international symposium on bilirubin metabolism in the newborn* Jerusalem April 1974 The papers deal almost exclusively with two subjects—phototherapy and bilirubin binding to albumin

Although the efficacy of phototherapy in reducing the serum bilirubin level in preterm infants has been established for several years this book points to many unsolved questions and answers some of them The practical application of phototherapy is described in some detail The use of the spectroradiometer for measuring the light energy is advocated other methods being of no value in this context The clinical effect of continuous versus intermittent irradiation is examined Acute side effects such as increased insensible water loss and reduction of whole blood riboflavin and G-6 PD levels are reported indicating a wide range of biological effects of light An earlier report on long term growth retardation in treated infants has not been confirmed however Other hypothetical side effects are discussed but obviously harmful long term effects of phototherapy have not been described so far and none of the contributors to this symposium advises against its use Despite the use of advanced physiochemical methods in the study of bilirubin degradation products it has not been possible to determine the precise effect of light on bilirubin metabolism

The binding of bilirubin to albumin has been studied extensively in recent years and reports on such investigations constitute the major part of this book The displacement of bilirubin from albumin by drugs and other substances can be measured *in vitro* and several methods are presented Today a new drug should not be administered to newborn infants unless its bilirubin displacing capacity has been tested in an *in vitro* system

The finding of bilirubin encephalopathy at low bilirubin levels in preterm infants makes determination of the reserve albumin binding capacity for bilirubin an urgent task The Sephadex gel filtration technique the object of several reports seems promising The evaluation of the method is hampered by the lack of follow-up investigations and by co-existing pathologic conditions

This book is a comprehensive account of the knowledge about phototherapy and bilirubin binding at the time of the symposium and it should for several years remain a valuable source of information and references for those interested in these fields

Sven Petter Fallstrom

Yash Paul *A manual of examination of the newborn* 83 pp illus William Heinemann Medical Books Ltd London *1976 £2 25 ISBN 0-433 24740-1*

Numerous valuable textbooks on neonatal medicine are available at present In most of these books the method for examining the infant is only briefly described and the reader expects from the title that the current book will improve on this previous weakness Unfortunately with the sole exception of the neurological examination which is presented in detail no detailed description is presented of the examination techniques i e how to examine the abdomen how to examine the scrotum in cases of swelling how to perform transillumination etc On the other hand the author indicates that he has stressed the interpretation of signs and symptoms which is a valuable contribution

The manual contains ten chapters these concerning general evaluation the skin the head the neck and face the extremities and spine the abdomen the respiratory system the cardiovascular system the genitalia the neurological evaluation and the assessment of gestational age Each chapter is subdivided on the basis of either anatomical descriptions or symptoms this manner of organization makes it difficult at times for the reader to find a specific topic of interest and descriptions are sometimes found in unexpected locations For example the Silverman scoring method is described in the section termed differential diagnosis in the chapter on the respiratory system and muscular hypotonia is presented in the chapter on general evaluation but not in the chapter on the neurological evaluation

The author s selection of signs and symptoms is at times rather surprising For example Naevus of Ota and Naevus of Ito (?) are described but more common findings like vaginal polypus deviation of nasal septum and muscular hypotonia are not included

Nevertheless the book might be of help especially to inexperienced doctors in the interpretation of signs and symptoms Recommendations for later editions would be to add a section on examination techniques to improve the classification of signs and symptoms and to extend the index

Preparation of Manuscripts

Contributors are requested to pay particular attention to the following rules governing the preparation of manuscripts *Failure to follow these rules is a frequent cause of delay in the publication of articles and may result in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate to the office of the Managing Editor Professor C G Bergstrand Department of Paediatrics Malmö Allmänna Sjukhus S-214 01 Malmö Sweden mailed flat and transmitted by first class mail They should be double spaced typewritten on one side of the paper with wide margins Authors should exercise particular care in the preparation notation and description of figures and tables Each table must be accompanied by a descriptive title typed above the table to which it refers A suitable legend *must be provided for each* figure Oversized original illustrations should be photographed and a print on glossy paper submitted. A separate *title page* is necessary and should bear *a) the title b)* the initials and names of the authors c) the institution of origin Below the list of references the principal author should state his address to which the proofs are to be sent

A short abstract not exceeding 200 words *must* accompany each manuscript informing about problem methods results and conclusions Unexplained abbreviations and references are not allowed The abstract must be typed on a separate sheet and styled as illustrated

ABSTRACT Köhler L and Holst K (Department of Paediatrics University Hospital Lund Sweden) Dental health of four year-old children Acta Pædiatr Scand 00

An unselected population of 1 567 four year-old children

KEY WORDS Pre-school children caries gingivitis

A *summary* is usually not necessary but may be allowed if the author (or the Editor) finds it essential A summary should be typed immediately after discussion

References to the literature should be limited to those quoted by the author The reference list should be arranged alphabetically and numbered giving name of author (authors) initials full title of paper name of journal abbreviated in accordance with the *style of Index Medicus* (*New Series*) followed by the volume number page number and year *In this system of abbreviation periods are omitted*

1 Brecher G & Stohlman F Jr Humoral factors in erythropoietin. *In L. M Tocantins & R. Penn (eds.) Progress in hematology* Grune & Stratton, New York 1959 p 110
2. Smith, C. A. *The physiology of the newborn infant* Thomas, Springfield, Ill 1967 3rd ed. vol. 2 p 120
3 Vedra, B & Ulrych, J., *Anaerobiosis in normal* and asphyxiated premature newborns. 2. Four approaches. *Acta Paediatr Scand* 49 129 1960

Italics are marked in the manuscript by underlining. *Abbreviations* must conform to accepted standards When in doubt authors are advised to consult a recent issue of the Journal The SI system should be used. Laboratory slang clinical jargon and colloquialisms must be avoided

Proofs and Reprints Galley proofs will be sent to the principal author by the printer The master proof *should be returned to the Managing Editor* together with the manuscript within three days and by air mail if received by air mail Reprints of articles published must be ordered by separate application from *Almqvist & Wiksell, S 751 81 Uppsala Sweden* to whom cheques money orders and drafts should be made payable

Manuscripts books for review and correspondence *relating to the editorial management should be sent* to the Managing Editor Department of Paediatrics Malmo Allmänna Sjukhus S-214 01 Malmö Sweden. Published manuscripts are not returned unless requested

ANDERS SPARRMAN AND HIS TRANSLATION OF ROSÉN VON ROSENSTEIN'S TEXTBOOK ON CHILDREN'S DISEASES DURING CAPTAIN COOK'S EXPEDITION TO THE ANTARCTIC REGIONS AND ROUND THE WORLD (1772–1775)

BO VAHLQUIST

Short biography

Anders Sparrman was born in 1748 in Tensta a parish outside Uppsala His father was a clergyman Anders was registered at the University of Uppsala at an early age in 1762 There is reason to believe that he only entered into more systematic studies after returning home in 1767 from his long voyage to China (see below) In 1768 he was enlisted for work in the surgical profession In that same year he defended under the presidium of Linnaeus a thesis *pro exercitio Iter in Chinam* (6) Some years later in 1775 when he was still in S Africa the degree of Doctor of Medicine was conferred upon him *in absentia* in Uppsala

Sparrman was elected a member of the Royal Academy of Sciences in 1776 This distinction was soon followed by others making him an honorary member of a number of learned societies both at home and abroad (5) In 1780 he became Curator of the Cabinet of Curiosities (Naturaliekabinettet) of the Academy In 1790 he was appointed Professor of Historia Naturalis and Pharmacy at Stockholm a position which he retained until 1803 At the same time he was also named Assessor of the Collegium Medicum and he still held this position when the Collegium was reorganized in 1813 In his later years he acted as a physician to the indigent in the parish of St Clara in Stockholm He died in 1820

Anders Sparrman in his manhood days holding the position as Curator of the Cabinet of Curiosities at the Royal Academy of Sciences

The translation of the Rosen von Rosenstein book

Like so many other disciples of Linnaeus Sparrman as a young man made long voyages At the age of 17 he sailed aboard the Swedish

This article has been written following a proposal by Professor W J Darby President of the Nutrition Foundation New York It will form part of the introduction to a forthcoming facsimile reprint of the English edition (1776) of *The Diseases of Children and their Remedies* to be published by Johnson Reprint Corporation New York

Be so kind and remember me with news from Europe especially literary ones Please do promote my translation of Rosen At my return from my journey I will write you a long epistle about it

And after his return to Sweden on August 7 1776

Many and very many thanks for Rosén s translation

In the autumn of 1776 Sparrman went to London for a few months Apparently the translated edition although dated 1776 had still not been published before he left for Swe den Anyhow he does not seem to have procured a copy of the completed work (4) in London because in a letter to Forster of 15 March 1777 he writes

please to send me a copy or two of Roseen I will give one to the King s library

And on March 27 1777

And wish to hear if the Parcel has arrived at Gothenburg and hope I shall see a specimen of my translation of Roseen that I may shew it the Swed Acad of Sciences and present it to the King as another Specimen of my capacity for I am really proud of knowing the Engl language as well as I do and people here look upon it as a terrible difficult thing to write—as it is indeed

On July 25 1777

Roseens book I have been looking at also a little and find that I have forgotten a great deal of English to write it especially Please to excuse my blunders here If you could send me the manuscript of Roseen some time or other I could remember several things better by the cor rections and keep it for my grand Childern if I ever have any *Pray what do the Engl Physicians say of my trans lation of Roseen?*—I was told That Roseen had written a Pharmacopy of 300 pages in 8° only to compositions as for one travelling by land or living in the coun *try—suffi* cient rules it be looked upon here as a Masterpiece the whole medicine comprehended in a nut —Pray is it trans lated into English al eady or would it be wo th wh le at any time

The correspondence continues with a few more letters until Sept 5 1780 but no more reference is made to Rosen s works

Sparrman refers here to Rosen s Hus och rese apoteque (House and Travelapotheque) This work of 11? pages first published in 1765 was enthusiastically received in Sweden and later on translated into Danish and German

Some further notes on Sparrman s life

After his long and adventurous travels in 1772–76 and the following London visit Sparrman went abroad only once more In 1787–88 he was a member of a small group of Swedes travelling on Royal command to West Africa with the aim of finding out whether in the in terior of Senegal or adjacent areas the establishment of a Swedish colony could be meaningful and practicable

The attempt was a failure however but ex perience from this expedition may have con tributed further to making him an ardent sup porter of the anti slavery movement

All his life Sparrman held a vivid interest in Botany and Zoology At times he com plained that his fellow countrymen may have felt that his interest in insects wild game and other fauna and flora dominated over his work as a physician His salaried work and his writ ing and translation of books gave a meagre in come He lived a spartan life as a bachelor

His *magnum opus is of course* the great narrative of his travels in S Africa (7) This appeared in Swedish in 1783 and the many foreign translations that were published in 1784–89 made him a famous man Another *narrative* dealing with his voyage with Cook appeared many years later (8)

Sparrman also published a number of trans lations and other works including two colour plate books on birds which are now highly treasured by collectors During his lifetime many distinctions were bestowed on Sparrman for his contributions to Science His portrait was included in the folio work *Les Hommes Illustres Vivants* Paris 1787

ACKNOWLEDGEMENT

I should like to express my thanks to Mr O A Hagelin Stockholm for stimulating discussions

1 Forster J G *Briefwechsel* F A Brockhaus Leipzig 1829

East India Company ship *Stockholm Slott* to Canton China This voyage which started in 1765 lasted a year and a half The Swedish captain C G Ekeberg took a personal interest in Sparrman and was instrumental in preparing for his trip to S Africa in 1772 Seconded by Linnaeus he got a free passage to the Cape Colony in order to take up work as a tutor to the children of the Vice governor at Bay Falso Naturally his main aim was to collect in his leisure hours and bring back home all kinds of botanical specimens He reached the Cape on April 14 1772

When Sparrman left Sweden the third and enlarged edition of Rosen von Rosenstein s textbook had just appeared (3) As we shall see he evidently took with him a copy of the book The idea of preparing a translation into English must have come to him later how ever because when caught by a surprise visit by the renowned scientists (father and son) Johann Reinhold and Georg Forster and in vited to join them on Captain Cook s second expedition he enters in his diary (7 p 83) that his ignorance of the English language was a major reason for hesitation

After a restless night however Sparrman decided to accept the invitation and break off temporarily his stay in S Africa Thus when the *Resolution* left the Cape on 22 November 1772 bound for the Antarctic Sparrman was on board Sea sickness befell him almost im mediately and the months and years to follow brought many discomforts at times real hard ships

Many years later he wrote (8 p 22)

> Having hitherto been accustomed to sailing only in a large Swedish East Indiaman I found myself thrown about and buffetted by every wave that surged under our small ship

From another source (2 pp 87–88) we have some laconic notes on his living quarters on board the ship He

> was stowed in the steerage with the books [He] had a pretty wet time in his quarters throughout the voyage

As regards the circumstances surrounding the translation of the book we have an in teresting though brief description in the narra tive of his S African travels (7 vol 1 pp 131–132) When dealing with Preparations for the African Expedition March 1775, he writes as follows

> My travelling purse was farther fortified by a lucky specu lation in commerce and likewise with sixty ducates for my English translation of our able Swedish physician VON ROSENSTEIN's *Treatise on the Diseases of Children* This work I undertook and finished in the last year of our cruising in the South Sea mostly in the rougher climates as I at that time was the least taken up with business of any other kind except that of writing though even in this case I was not unfrequently obliged on account of the stormy weather to cling with my legs round the foot of the table and hold myself fast with one hand in order to be able to write with the other I take this opportunity of acknowledging my obligations to Messrs Forster for various alterations they were so kind as to bestow on the translation here alluded to which my slender knowledge of the English tongue made extremely necessary as like wise for their taking care of the impression of it at London in the year 1776

It is quite conceivable that the initiative to translate Rosen s textbook into English may have arisen from discussions between Sparr man and Messrs Forster Young Georg For ster had already gained experience as a translator and he and his father may well have been aware of the fact that Rosen s textbook which first appeared in monograph form in Sweden in 1764 had within a few years been translated into several foreign languages (Ger man Dutch and Danish) Translations into several other languages were to follow (French Italian Hungarian) but only after the English edition had appeared

When the *Resolution* homeward bound left the Cape on 27 April 1775 Messrs Forster were on board and the translated manuscript with them whereas Sparrman was to remain in S Africa for another year

After their parting in April 1775 Sparrman continued to correspond with Georg Forster for a number of years Thirteen letters from Sparrman to Forster were published in 1829 (1) In these letters Rosen s book is referred to on several occasions Thus in the only letter from Sparrman s second period in S Africa he writes on 27 August 1775

Be so kind and remember me with news from Europe especially literary ones Please do promote my translation of Rosen At my return from my journey I will write you a long epistle about it

And after his return to Sweden on August 7 1776

Many and very many thanks for Rosén s translation

In the autumn of 1776 Sparrman went to London for a few months Apparently the translated edition although dated 1776 had still not been published before he left for Sweden Anyhow he does not seem to have procured a copy of the completed work (4) in London because in a letter to Forster of 15 March 1777 he writes

please to send me a copy or two of Roseen I will give one to the King s library

And on March 27 1777

And wish to hear if the Parcel has arrived at Gothenburg and hope I shall see a specimen of my translation of Roseen that I may shew it the Swed Acad of Sciences and present it to the King as another Specimen of my capacity for I am really proud of knowing the Engl language as well as I do and people here look upon it as a terrible difficult thing to write—as it is indeed

On July 25 1777

Roseens book I have been looking at also a little and find that I have forgotten a great deal of English to write it especially Please to excuse my blunders here If you could send me the manuscript of Roseen some time or other I could remember several things better by the corrections and keep it for my grand Childern if I ever have any *Pray what do the Engl Physicians say of my translation of Roseen?*—I was told That Roseen had written a Pharmacopy of 100 pages in 8 only to compositions as for one travelling by land or living in the coun ry—sufficient rules it be looked upon here as a Masterpiece the whole medicine comprehended in a nut —*Pray is it translated into English already? or would it be worth while at any time?*

The correspondence continues with a few more letters until Sept 5 1780 but no more reference is made to Rosen s works

FACTOR XIII (FIBRIN STABILISING FACTOR) IN HENOCH SCHÖNLEIN S PURPURA

PER HENRIKSSON ULLA HEDNER and INGA MARIE NILSSON

From the Department of Paediatrics and the Coagulation Laboratory University of Lund Allmänna Sjukhuset Malmö Sweden

ABSTRACT Henriksson P Hedner U and Nilsson I M (Department of Paediatrics and Coagulation Laboratory University of Lund Allmänna Sjukhuset Malmö Sweden) Factor XIII (fibrin stabilising factor) in Henoch Schonlein s purpura Acta Paediatr Scand 66 273 1977.—In 13 out of 17 consecutive children with Henoch-Schonlein s purpura the factor XIII determined with the dansyl cadaverine method was found to be decreased during the acute phase The decrease is assumed to be due to a specific degradation by proteolytic enzymes liberated from inflammatory cells with defective local haemostasis as a result This assumption is strengthened by the observation that treatment with factor XIII combined with an antifibrinolytic drug controlled life threatening gastro-intestinal bleeding in one of the patients It would therefore appear that such treatment might offer a new possibility of controlling severe haemorrhages in Henoch-Schonlein s purpura

KEY WORDS Henoch-Schonlein s purpura abnormal proteolysis factor XIII

Henoch Schonlein s purpura (anaphylactoid purpura allergic purpura) is characterised by haemorrhagic skin lesions abdominal symptoms including gastro intestinal bleeding renal involvement with proteinuria and haematuria and swelling of joints The symptoms are ascribed to generalised inflammation of the arterioles and capillaries In this syndrome haemostasis assessed with ordinary methods is normal and thereby distinguishes the condition from primary haemorrhagic disorders (17)

It has recently been shown that proteolytic enzymes liberated from inflammatory or damaged tissue cells can specifically degrade certain factors in the coagulation system such as fibrinogen factor V and factor XIII (12 23 24) In patients with erosive gastritis characterised by diffuse haemorrhage from an inflamed gastric mucosa local fibrinolysis in combination with a low factor XIII concentration has recently been shown to contribute to local defect in the patients haemostasis (21)

A similar mechanism was thought to play a role in the pathogenesis of the bleeding symptoms in Henoch Schonlein s purpura We therefore studied a series of patients with this syndrome with special reference to the factor XIII concentration

CLINICAL MATERIAL

The material consisted of 17 consecutive patients (12 boys and 5 girls) aged 2 1/2 to 13 years with Henoch Schonlein s purpura Clinical data and routine haematologic findings are summarised in Table 1 Blood was obtained by puncture of a peripheral vein with the silicone technique and citrated plasma and serum were prepared in the way previously described (19 22)

METHODS AND MATERIALS

Factor VIII clotting activity (F VIII C) was determined according to Nilsson et al (19) factor VIII related antigen

(F VIIIR AG) immunochemically with Laurell's rocket technique (13), *fibrinogen* according to Nilsson & Olow (20), *factor XIII* (fibrin stabilising factor = FSF) according to Lorand et al (16) as modified by Henriksson et al (11) and expressed as FSF units/l citrated plasma $\times 10^3$, *fibrinolytic activity* in the circulating blood on fibrin plates (resuspended euglobulin precipitate) according to Nilsson & Olow (20) and *fibrin/fibrinogen degradation products (FDP)* with the immunochemical method of Nilehn (18). The FDP were determined in serum obtained from blood collected in tubes containing thrombin (3 NIH U/ml blood) and EACA (5–10 mg/ml blood), *ethanol gelation test* according to Godal et al (8), *plasminogen* with an immunochemical method according to Ganrot & Nilèhn (7), *platelet counts* according to Bjorkman (1), *α_2-macroglobulin (α_2M)* as described by Ganrot (6) and *antithrombin III (AT III)* immunochemically (9). *Factor XIII concentrate*: factor XIII rich fibrinogen (Fibrinogen Kabi 1 g/100 ml 48 FSF U/ml and fraction I-0 (AHF Kabi 153 FSF U/ml).

RESULTS

The results of coagulation and fibrinolytic studies are summarised in Table 2. *Factor XIII was low* (below 12 FSF U/l×10³) in 13 of the 17 patients. F VIII C and F VIIIR AG were within normal limits or slightly increased. The *plasminogen* levels were normal except in the severely affected child (No 1), which is described separately below. No increased *fibrinolytic activity* in blood was observed on fibrin plates, except in one case (No 7). *FDP* appeared in small amounts in serum from 2 patients, including the one with

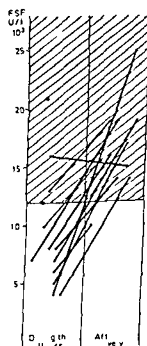

Fig 1 Factor XIII levels during the acute phase of the disease and after recovery

The observations open a new approach to the treatment of severe haemorrhages in these patients The concentrate must be given frequently during the acute phase (Fig 2) owing to the extreme shortening of the half life of factor XIII normally estimated to be 4–5 days (14) and it should be combined with an anti fibrinolytic drug due to the increased susceptibility of fibrin to local fibrinolysis when factor XIII is low

mal factor XIII concentrations except one patient (No 6) who had 6 FSF U/l×10³ during the acute phase and still showed a subnormal value (10 FSF U/l×10³) after her recovery

Case I

A 9 year-old boy was admitted to our hospital with full blown clinical picture of Henoch Schonlein s purpura and profuse gastro intestinal bleeding He had received 6 units of bank blood within the last 5 hours before admission Various relevant data noted in the course of the disease are given in Fig 2 Therapy was focused on his low factor XIII levels and his raised fibrinolytic activity indicated by the low fibrinogen and plasminogen levels He was thus given factor XIII concentrates (total dose 245 000 U FSF which corresponds to the FSF in about 12 250 ml plasma over the first 3 weeks) Tranexamic acid (AMCA Cyclokapron Kabi) was given parenterally during the first 9 days (total dose 12 g) followed by 6 g a day *by mouth for the following 20 days Immediately* after the beginning of this treatment the gastro intestinal bleeding stopped Factor XIII increased to normal but on withdrawal of factor XIII concentrate for one week it again fell to subnormal level At follow up several months after his recovery the factor XIII level was normal (25 FSF U/l×10³)

DISCUSSION

Factor XIII was low in 13 out of the 17 patients *with Henoch Schonlein s purpura The* normal or slightly decreased values were found in patients who were only mildly ill It seems likely that factor XIII is often low in these patients also in those in whom the haemorrhage is not severe However 5 of the 13 patients who had low factor XIII levels developed anaemia

Though low these factor XIII levels per se are still high enough for normal haemostasis *It has however been shown that in patients* with a low factor XIII level the fibrin clots formed are not fully stabilised and are abnormally susceptible to fibrinolytic attacks (2 5 15) Decreased factor XIII must therefore render the patients more susceptible to local fibrinolysis or other types of abnormal proteolysis and thereby increase the tendency of inflamed mucosa to bleed This mechanism could explain the immediate effect of the treatment *given in case* 1 (factor XIII concentrate and tranexamic acid) Antifibrinolytic treatment therefore seems to be one important measure in the treatment of these patients *The other* and equally important measure is repeated substitution with factor XIII concentrate in order to make sufficient available for fibrin cross linking

Factor XIII has been claimed to decrease in conditions associated with an activation of the coagulation system (3) Of 19 patients with diseases complicated by an abnormal proteolytic activity (fibrinolysis and/or an activated coagulation) we found the factor XIII level to be low in 15 (10) In the present study however no other signs of thrombin activity such as decreased levels of fibrinogen F VIII C and pla*telets and positive ethanol gelation test could* be found In one of our patients (Nr 7) it could not be excluded that a generalised fibrinolytic activity had contributed to the pattern found But other authors have not reported any decrease in factor XIII in fibrinolytic states not even during urokinase treatment (3)

The findings of an exclusive decrease of factor XIII in moderate or severe Henoch Schonlein s purpura suggest some specific degrada*tion of factor XIII Such degradation* has been observed in leukemia (4) erosive gastritis (21) and Weber Christian disease (nonsuppurative nodular panniculitis) (12) Proteolytic enzymes from leukocytes have been found to degrade factor XIII fibrinogen and factor V *in vitro* (24) The low factor XIII levels observed in Henoch Schonlein s purpura might therefore be the result of a destruction by proteases liberated from leukocytes during the inflam*matory* process around innumerable arterioles and capillaries throughout the body The fact that one of the patients (Nr 1) had so low values of factor XIII on admission in spite of the administration of substantial amounts of blood within a short time speaks in favour of an ongoing specific degradation of factor XIII *in the circulation So does* also the persistent high turnover rate of factor XIII in this patient even after the bleeding had stopped thus excluding impaired production as an important cause of the lowness of factor XIII

The observations open a new approach to the treatment of severe haemorrhages in these patients The concentrate must be given fre quently during the acute phase (Fig 2) owing to the extreme shortening of the half life of factor XIII normally estimated to be 4–5 days (14) and it should be combined with an anti fibrinolytic drug due to the increased suscepti bility of fibrin to local fibrinolysis when factor XIII is low

CONGENITAL IMMUNODEFICIENCY AND AGRANULOCYTOSIS (RETICULAR DYSGENESIA)

R J HAAS [1] D NIETHAMMER S F GOLDMANN W HEIT
U BIENZLE and E KLEIHAUER

From the Department of Paediatrics Division of Hematology University of Munchen and the Department of Paediatrics University of Ulm/Donau Fed Rep Germany

ABSTRACT Haas R J Niethammer D Goldmann S F Heit W Bienzle U and Kleihauer E (Departments of Paediatrics Universities of Munchen and Ulm Fed Rep Germany) Congenital immunodeficiency and agranulocytosis (Reticular dysgenesia) Acta Paediatr Scand 66 279 1977—A patient is presented who manifested the typical clinical and pathological features of congenital immunodeficiency and agranulocytosis (reticular dysgenesia) Treatment under gnotobiotic conditions enabled the measurement of immunolog ical parameters up to the 17th week of life with the following results negative skin tests low response to phytohaemagglutinin weak response in the mixed leukocyte culture and very few E rosettes Peripheral lymphocytes and lymphocytes in the lymphatic tissues were markedly decreased Humoral immunoglobulins and plasma cells in the organs were decreased The in vitro culture of hemopoietic cells showed a diminished content of myelopoietic progenitor cells (committed stem cells) It is concluded that the disease may be primarily a defect of stem cells with regard to differentiation in myelopoiesis or lymphopoiesis

KEY WORDS Reticular dysgenesia immunodeficiency stem cell defect

In 1959 de Vaal & Seynhaeve (15) described two cases of a disease which they termed reticular dysgenesia A third case was re ported by Gitlin et al (7) and a fourth by Alonso et al (2) These infants died 5 to 15 days after birth Although no immunological studies were carried out necropsy suggested a generalized immune deficiency disorder We have recently observed a newborn with reticu lar dysgenesia The patient lived until the age of 17 weeks under gnotobiotic conditions enabling us to measure immunological para meters

CASE REPORT

Family history

Consanguinity was demonstrated in the family history as shown in Fig 1 Four relatives died during the first year of life as a result of infections but no autopsies were done

Supported by SFB Contract No 112 of Deutsche For schungsgemeinschaft

Patient history

V V was born at term after an entirely uneventful preg nancy with a birth weight of 2500 g Immediately after birth he developed severe diarrhea and was transferred to our hospital at the age of 12 days Examination showed dehydration No thymus was apparent Cultures from the skin body orifices faeces and urine grew numerous or ganisms including *Staph aureus Staph epidermidis Klebsiella Escherichia coli Enterococcus Pseudomonas β-haemol streptococcus* and *Strept viridans* The cerebrospinal fluid and the blood were sterile Decon tamination of the microflora was attempted by surface disinfection with Tego® (Goldschmidt) and administration of local antibiotics and non absorbable antibiotics includ ing fungistatics In addition carbenicillin oxacillin and gentamycin were administered intravenously As a result all bacteria were eliminated except Klebsiella which was suppressed but not completely eliminated After decon tamination at 19 days the patient was placed in a plastic isolation system designed and constructed in our hospital (6) He continued to receive antibiotics and fungistatics

Under these conditions the infant remained well until 15 weeks old when he weighed 3700 g He then suddenly deteriorated with a high intermittent fever up to 41 C and severe diarrhea Ronchi and inspiratory rales were heard over both lungs and there was marked inspiratory retrac tion Klebsiella was cultured from blood stool urine and

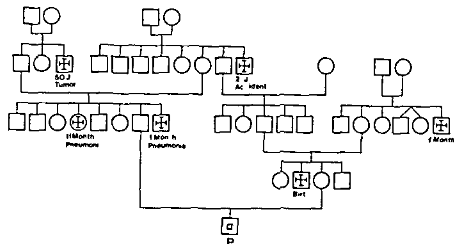

Fig 1 Pedigree of family V

in smears from the body orifices The patient died when he was 17 weeks old

Laboratory findings

General laboratory features Red cell counts Hb MCHC and reticulocytes were within normal range from birth until the 15th week During the last two weeks of life the child had septicaemic thrombocytopenia with lowest values in the order of 2×10^9/l and severe anaemia developed The white blood cell count was persistently below 1×10^9/l with marked lymphopenia Although most of the leucocytes were mononuclear cells some mature granulocytes were seen in the stained smears (Fig 2)

Total serum protein was around 60 g/l Normal values were found for sodium calcium potassium phosphorus chloride alkaline phosphatase and blood urea nitrogen levels Haemoglobins were normal with about 0 53 units HbF measured at birth

Bone marrow Smears of aspirated bone marrow were made when the boy was 6 and 12 weeks old Both smears *showed normal erythropoiesis and megakaryopoiesis* There were abundant promyelocytes but no distinct myelocytes metamyelocytes band or lobulated forms The number of reticular cells was high and many mast *cells were present*

Special investigations

Determination of serum factors The immunoglobulins were determined by a radial immuno-diffusion technique (9) using Partigen® plates (Behringwerke Marburg)

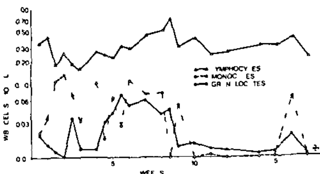

Fig 2 White blood cells $\times10^9$/l

Skin tests for delayed hypersensitivity The dinitrochlorobenzene test was performed according to the method of Aisemberg (1) A Candida skin test was done with Candida albicans extract 1 10 (Hollister Stier) administered in 0 1 ml

Lymphocyte cultures The in vitro response of lymphocytes to phytohemagglutinin (PHA) was tested with lymphocytes separated from heparinized blood using the method of Bøyum (4) 10^6 lymphocytes were cultured in 1 ml MEM S (Gibco) supplemented with 20% inactivated fetal calf serum 1% L glutamine and antibiotics PHA (Wellcome) was used at a final concentration of 1 125 The cells were harvested after 96 hrs

Mixed lymphocyte cultures were set up with $0\ 75\times10^6$ responder cells and $0\ 75\times10^6$x irradiated (2 000 rads) stimulator cells and harvested after 144 hrs at 37°C in 5% CO_2 0 06 μCi/mMol $2-{}^{14}C$ thymidine was added for the last 16 hrs of culture The uptake of the isotope was determined by liquid scintillation counting T-cells were detected by rosette formation with sheep erythrocytes *Lymphocytes were washed three times in gelatin veronal* buffer and resuspended in Hanks solution at a concentration of 2×10^6/ml The lymphocytes were incubated with sheep red blood cells for 15 minutes at 37°C and left overnight at 4 C (8)

Soft agar culture of bone marrow (BMC) and white blood cells (WBC) Heparinized bone marrow and peripheral leucocyte specimens obtained at the age of 12 weeks and before death were allowed to sediment at 1 G for 40 min at 4 C The supernatants were washed twice *with buffered balanced salt solution and the resulting cell* suspensions resuspended in culture medium (McCoy s 5A Gibco 0 3% Bacto Agar Difco) supplemented with 15% fetal calf serum

Plating of the hemopoietic cells was performed according to the procedure of Robinson et al (12) described in detail by Metcalf (10) All agar cultures were set up in triplicate and incubated in airtight glass containers at 37°C with 3% CO_2 and high humidity After 10 days incubation all aggregates of more than 50 cells were counted as colonies

Postmortem findings

The *thymus* consisted of a small number of fibrotic lobules No lymphocytes or Hasall s bodies were de

Stimulation index is the ratio of c p m of PHA stimulated cells to control cells

RESULTS

Immunological studies The results of the immunological studies are recorded in Tables 1 and 2 Serum immunoglobulins were decreased except for IgG levels recorded when the boy was 2 weeks old The percentage of peripheral blood lymphocytes was very low as is detailed in Fig 2 Data related to the thymus dependent system show that delayed hypersensitivity reactions were absent The in vitro lymphocyte response to PHA was markedly decreased when evaluated by thymidine incorporation The response of lymphocytes in mixed leucocyte culture was also reduced The percentage of lymphocytes forming E rosettes was very low The tests of cellular immunity were performed when the boy was 8–12 weeks old

Stem cell assay As shown in Table 3 the incidence of colony forming cells (CFCs) per 2×10^5 BMC of both the 2 year old and the healthy adult hematological patient was found to be within the normal range In addition the colony counts in WBC cultures of the control

Table 3 *Incidence of CFCs in the bone marrow and peripheral blood*

	No of CFCs per ?×10⁵ BMC	No of CFCs per 1×10 WBC
V V (1? weeks old)	16 (15–17)	No colonies
V V (preterminally)	No colonies	N D
Hematologically healthy controls		
(years old)	66 (63–70)	N D
(43 years-old)	54 (48–58)	1? (6–13)

were consistent with the usual findings obtained with healthy volunteers In the patient (V V) a substantial reduction of CFCs was found in the cultures at 12 weeks and no colony formation was observed in peripheral WBC cultures Immediately before death all cultures were negative All the colonies derived from the bone marrow specimen at 12 weeks were small in size (50–150 cells/colony) compared to the controls (50–2 000/colony) All aggregates consisted of granulocytic cells as far as could be determined by orcein staining

DISCUSSION

The histopathological findings in our patient were essentially the same as those described in the 4 known cases of the disease (2 7 15)

In our case the in vivo and in vitro tests of the cellular immunity were found to be decreased DNCB and candida skin test were negative and the response to phytohaemagglutinin stimulation was very low In the mixed leucocyte culture there was a weak response and the number of circulating lymphocytes was low (5) At postmortem depletion of lymphocytes in the lymphatic tissues and thymic aplasia were found The T cell defect was specifically proven by the low number of peripheral lymphocytes forming E rosettes Humoral immune response was also decreased as indicated by low serum Ig levels and the absence of plasma cells in the organs The IgG level found can be attributed to maternal IgG (16)

Experimental data (11) and a number of successful bone marrow transplantations in children with congenital combined immunodeficiencies suggest that the primary lesion in these patients is a stem cell defect (3) It has been shown that the pluripotent stem cell is not only the precursor in haemopoiesis but also supplies progenitors of the lymphatic cell series (13)

Our case is of particular interest with respect to the understanding of immunological diseases suspected to be caused by a stem cell defect since in addition to the combined immunodeficiency the patient suffered from agranulocytosis The in vitro colony forming cells (CFCs) are considered to be progenitors in granulopoiesis in the sense that they are committed stem cells As progeny of the pluripotent stem cells the CFCs are the most immature cells detectable in human hemopoietic cell suspension with the assay systems available It could be shown that the myelopoietic progenitor cell content (CFCs) was diminished in the patient s bone marrow when the infant was 12 weeks old and absent before death

The following possible explanations for this finding can be considered

(*a*) There may be a genetic defect of pluripotent stem cells with regard to differentiation in myelopoiesis or lymphopoiesis

(*b*) Microenvironmental factors could inhibit the differentiation of stem cells in myelopoiesis (14)

However as the microenvironmental factors in myelopoiesis are probably related to interactions between adjacent bone marrow stroma cells and as our test system was done in vitro, it is unlikely that the latter mechanism plays a role in these disorders

In our case the in vivo and in vitro tests of the cellular immunity were found to be decreased DNCB and candida skin test were negative and the response to phytohaemagglutinin stimulation was very low In the mixed leucocyte culture there was a weak response and the number of circulating lymphocytes was low (5) At postmortem depletion of lymphocytes in the lymphatic tissues and thymic aplasia were found The T cell defect was specifically proven by the low number of peripheral lymphocytes forming E rosettes Humoral immune response was also decreased as indicated by low serum Ig levels and the absence of plasma cells in the organs The IgG level found can be attributed to maternal IgG (16)

Experimental data (11) and a number of successful bone marrow transplantations in children with congenital combined immunodeficiencies suggest that the primary lesion in these patients is a stem cell defect (3) It has been shown that the pluripotent stem cell is not only the precursor in haemopoiesis but also supplies progenitors of the lymphatic cell series (13)

Our case is of particular interest with respect to the understanding of immunological diseases suspected to be caused by a stem cell defect since in addition to the combined immunodeficiency the patient suffered from agranulocytosis The in vitro colony forming cells (CFCs) are considered to be progenitors in granulopoiesis in the sense that they are committed stem cells As progeny of the pluripotent stem cells the CFCs are the most immature cells detectable in human hemopoietic cell suspension with the assay systems available It could be shown that the myelopoietic progenitor cell content (CFCs) was diminished in the patient s bone marrow when the infant was 12 weeks old and absent before death

The following possible explanations for this finding can be considered

(*a*) There may be a genetic defect of pluripotent stem cells with regard to differentiation in myelopoiesis or lymphopoiesis

(*b*) Microenvironmental factors could inhibit the differentiation of stem cells in myelopoiesis (14)

However as the microenvironmental factors in myelopoiesis are probably related to interactions between adjacent bone marrow stroma cells and as our test system was done in vitro it is unlikely that the latter mechanism plays a role in these disorders

CORD BLOOD PORPHYRINS

A Quantitative Assay in Newborn Infants

F HANDA and S C SHARMA

From the Department of Dermato-Venereology Government Medical College and Rajendra Hospital Patiala Punjab India

ABSTRACT Handa F and Sharma S C (Department of Dermato-Venereology Government Medical College and Rajendra Hospital Patiala Punjab India) Cord blood porphyrins A quantitative assay in newborn babies Acta Paediatr Scand 66 285 1977 —A quantitative assay of free erythrocyte porphyrins was done in umbilical cord blood of 30 newborn babies by a spectrophotometric method The mean value of free erythrocyte protoporphyrin in umbilical cord blood was found to be 74.58 μg/100 ml packed erythrocytes and that of free erythrocyte coproporphyrin to be 0 77 μg/100 ml packed erythrocytes with a standard deviation of ±29 99 and ±1 48 respectively Relationship between free erythrocyte protoporphyrin and free erythrocyte coproporphyrin and their correlations with birth weight and sex of the newborn baby were found to be statistically significant

KEY WORDS Cord blood porphyrins free erythrocyte protoporphyrin free erythrocyte coproporphyrin newborns

Since the first detection of free erythrocyte porphyrin by Hijmans van den Bergh and Hyman in 1928 number of workers in various parts of the world have done quantitative estimation of free erythrocyte porphyrins in adults using different techniques Only few workers like Schwartz & Wikoff (4) Hsia & Page (1) Prato et al (2) Ventura & Meduri (5) and Wranne (6) have done quantitative estimation of free erythrocyte protoporphyrin (EPP) and free erythrocyte coproporphyrin (ECP) in umbilical cord blood No contribution from this part of the world has been made Hence the present study was carried out to establish normal levels of free erythrocyte porphyrins in umbilical cord blood of Indian newborn babies

MATERIAL AND METHODS

Rimington s (3) sensitive and reproducible technique based on the Broadsheet 70 (Revised Broadsheet 36) 1971 was used for the present study Umbilical cord blood samples were obtained from 30 newborn babies delivered in the Obstetric Department of this hospital Labour had not been difficult and asphyxia congenital anomaly disease or birth injury had not been observed in these babies Birth weights ranged from 000–3400 g with a mean of 2550 g

Deliveries occurred between 10 days before to 16 days after the expected date of delivery Haemoglobin in mothers ranged from 8 0–11 5 g/100 ml with a mean of 9 5 g/100 ml Age of the mothers was between 17 years and 35 years with a mean age of 24 5 years Parity of the mothers ranged from 1st–8th para with 3rd para as the mean parity Besides there was no Rh incompatibility between the mother and the newborn baby and no complication or medication (except supportive iron and vitamin therapy) during pregnancy

RESULTS

Normal levels of cord blood porphyrins

The mean EPP level was 74 58 μg/100 ml packed erythrocytes with a range of 33 10–141 22 μg/100 ml and mean ECP level was 0 77 μg/100 ml with a range of 0 00–4 49

Table 1 *Levels of cord blood porphyrins in various studies*

Study no	Authors	No of cases	ECP (μg/100 ml)		EPP (μg/100 ml)	
			Mean	*Range*	*Mean*	*Range*
1	Schwartz & Wikoff (1952)	2	–	8 1 5 3	–	178 69
2	Hsia & Page (1954)	6	1 5	0 6–2 8	125	63–203
3	Prato Mazza & Fiorina (1959)	10	7 9	4 4–12 6	72	46–116
4	Wranne (1960)[b]	20	2 8	1 1–7 2	54	32–135
5	*Present study (1976)*	30	0 77	0 00–4 49	74 58	33 10–141 22

Schwartz & Wikoff method of 1952 used and plasma included
[b] *Coproporphyrin included traces of protoporphyrin*

μg/100ml The highest EPP value of 141 22 μg/100 ml corresponded to the highest value of ECP 4 49 μg/100 ml and the second highest value of EPP 132 41 μg/100 ml also corresponded to the second highest value of ECP 4 09 μg/100 ml Correlation between EPP and ECP was found to be positive and statistically *significant (t value was 7 84 more than 2 05* table value t for 28 D F at $p=0$ 05)

Thus, increase in the levels of EPP corresponded to an increase in the levels of ECP

Correlation with sex of newborn baby

Protoporphyrin Mean level of EPP of 93 90 μg/100 ml with a range of 42 05–141 22 μg/100 ml in male babies more than the mean level of *EPP of 63 39 μg/100 ml with a range of 33 10–124 13 μg/100 ml in female babies and* this difference in the mean levels was statistically significant (t value was 2 59)

Coproporphyrin Mean level of ECP of 1 61 μg/100 ml with a range of 0 00–0 49 μg/100 ml in male babies was higher than the mean level of ECP of 0 28 μg/100 ml with a range of 0 00–2 96 μg/100 ml in female babies and this difference in the mean value was statistically significant (t value was 2 05)

Thus, the levels of EPP and ECP were higher in male as compared to female newborn babies

Correlation with birth weight

Protoporphyrin Correlation between EPP and birth weight was positive and statistically significant (t value was 7 05)

Coproporphyrin Correlation between EC and birth weight was positive and statistical significant (t value was 5 84)

DISCUSSION

In our study the highest and the second highe *EPP values correspond to the highest and th* second highest ECP values These findings ar similar to the findings of Wranne (6) But i addition we could establish a positive ar statistically significant correlation betwee EPP and ECP which is in contrast to the find ings of Wranne (6) who could not establis any such correlation Thus increase in th levels of EPP are accompanied by a co *responding increase in the levels of ECP in th umbilical cord blood*

In the present study we could also establis that values of EPP and ECP are significantl higher in the male than in the female newborn A possible explanation for this could be tha on an average the boys had a higher birt weight than the girls in our study

We could also establish a positive an significant correlation between the EPP an ECP values and the birth weight With highe birth weight there is a corresponding increas in the levels of EPP and ECP This may partl *be explained by an increased erythropoesi* caused by hypoxia in the heavier babies

Levels of EPP and ECP obtained in th present study are compared with the finding of earlier workers (Table 1) There is a wid *variation in the levels of EPP and ECP in um*

GENERAL HEALTH SCREENING OF FOUR YEAR OLDS IN A SWEDISH COUNTY

V A Strategy for Improving the Effectiveness and the Costefficiency of the Psychological Screening Program

C NILSSON C SUNDELIN and J-C VUILLE

From the Department of Paediatrics University Hospital Uppsala Sweden and the Institute of Social and Preventive Medicine University of Berne Berne Switzerland

ABSTRACT Nilsson C Sundelin C and Vuille J-C (Department of Paediatrics, University Hospital Uppsala Sweden and Institute of Social and Preventive Medicine University of Berne Berne Switzerland) General health screening of four year-olds in a Swedish county V A strategy for improving the effectiveness and the cost-efficiency of the psychological screening program Acta Paediatr Scand 66 289 1977.—Data presented in a previous paper pointed to the necessity for improving the overall sensitivity of the psychological screening program The present report indicates possibilities for such an improvement without changing the screening methods A comparison of the primary data of the true positives the false positives and all the negatives (non referred) revealed the necessity of more stringent referral criteria It is predicted that the systematic application of these criteria would result in an increase in the rate of true positives form 2 8 to 4 8% of the screened population In addition a strategy aiming at a reduction of the costs without deteriorating the effectiveness and based on a differential application of the various elements of the screening program is presented

KEY WORDS Pre school children psychological screening effectiveness cost-efficiency

In a previous report it was shown that the sensitivity of the program used for psychological screening within the context of a routine health examination of four year olds was not optimal (5) on the other hand the specificity and the positive predictive value as additional measures of effectiveness were considered to be acceptable (For definitions see ref 5) Two possibilities for improving the sensitivity were outlined

(*a*) Development of completely new instruments This would necessitate an assessment not only of the validity of the new methods in an experimental situation but also of their performance under the practical conditions of the field work Such a development may be extremely time consuming and it must be acknowledged that it might not bring about any improvement at all

(*b*) The yield of the methods now in use might be increased if more rigorous criteria could be established for the identification of those children who would benefit from referral to a specialist In the present report an attempt is made to define a number of such criteria on the basis of an analysis of the primary data of referred and non referred children

In addition a strategy allowing a reduction of the costs without deteriorating the results will be presented

METHODS

The methods used for screening and for the clinical assessment have been described previously (5) In essence

In addition a strategy allowing a reduction of the costs without deteriorating the results will be presented

METHODS

The methods used for screening and for the clinical assessment have been described previously (5) In essence

Table 1 *Definition of scores 0 1 and 2 in the four screening instruments*

Instrument	Score 0	1	2
Questionnaire	No problems according to the parents	Somewhat late in development and/or mild behaviour problems and/or latent need of help	Retarded development and/or severe behaviour problems and/or manifest need of help
Interview (sum of 27 items each item being coded 0 1 or 2)	0–3	4–9	10+
Examination/observation (sum of 5 items each item being coded 0 1 or 2)	0	1–5	6+
Physician s final rating	Normal for age	Somewhat deviant	Definitely deviant

the screening procedure was based on four different sources of data

(1) A simple questionnaire completed by the parents
(2) an interview conducted by the responsible nurse
(3) an examination of the child s development and direct observation of his behavior and
(4) an overall rating by the physician

Each source of data yielded a varying number of items In order to simplify the analysis the entire information from each method was reduced to a single score in the scale 0 1 2 according to the criteria shown in Table 1 The sum of the four scores will be called the total score

As a result of the clinical assessment each referred child was assigned to one of three categories healthy child at risk and definitely deviant An additional classification was made in the group of referred children according to the *main symptom* aggressiveness anxiety infantile symptoms (enuresis encopresis thumb sucking) restlessness/tension (hyperactivity sleep disturbance problems of contact tics nail-biting) The assignment to one of these classes was based on the number and the severity of the individual symptoms within each category as well as on the general prognostic significance of the symptoms (determined by common agreement of a group of child psychiatrists (4))

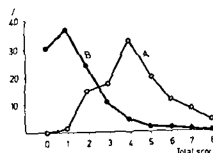

Fig 1 Percentual distribution of referred (open circles) and non referred (closed circles) children with respect to total score

MATERIAL

The present analysis is based on data concerning the children examined in 1969 and 1970 Of the 3 897 invited children 3 810 participated in the screening (=97 7%) For the present purpose only those with complete primary data are included The numbers may therefore vary somewhat between the different analyses depending on the variable(s) under study

Group A Children referred to the special assessment unit Originally this group comprised 158 children but only 127 of these were eventually seen by a specialist (5)

Subgroup A_T Referred children considered to be in need of treatment (child at risk and definitely deviant) $n=85$

Subgroup A_H Referred children declared healthy by the specialist $n=42$

Group B Non referred children with complete data $N=3\,008$

RESULTS AND DISCUSSION

1 *Total score in referred and non referred children*

In Fig 1 the distributions of the total score in groups *A* and *B* show a significant overlap This indicates that the decision as to whether or not a child should be referred to a specialist did not depend exclusively on the total number of problems symptoms or failures emerging in the test but rather *on the result of an overall* interpretation of the possible significance of these findings The details of this process are largely unknown but some special features may be elucidated from the available data

The following calculations were made under

Table 2 *Distribution of screening scores in referred children*

A_T = in need of treatment A_H healthy

Screening instrument	Clinical category	Screening scores (percentage distribution) 0	1	2	χ^2
Questionnaire	A_T n=7[illegible]	24.0	37.3	38.7	[illegible].85 *n s*
	A_H n=36	41.7	25.0	33.3	
Interview	A_T n=85	12.9	41.2	45.9	1[illegible].88
	A_H n=4[illegible]	40.5	33.3	6[illegible]	p<0.01
Examination & observation	A_T n=83	14.5	60.[illegible]	25.3	[illegible].43 *n s*
	A_H n=38	7.9	81.6	10.5	
Physician's rating	A_T n=84	39.3	29.8	30.9	0.36 *n s*
	A_H n=40	37.5	35.0	27.5	

the assumption that if additional children had been referred to the specialists because their data fulfilled certain criteria they would have been assigned to subgroups A_T and A_H in the same proportions as those children who had been referred in reality The observation (5) that a group of preschool children referred to the specialist team through mechanisms other than screening was composed of healthy at risk and deviant children in proportions equal to those of group A shows that this assumption is probably realistic

2 *Total score in subgroups A_H and A_T*

Fig 2 depicts a considerable overlap This is an important finding because it indicates that the total score alone is not a very useful measure for the precise identification of children who will eventually need treatment In the region of score 5 or more however the discrimination appears satisfactory Thus if all children who had accumulated scores of 5 to 8 had been included another 48 referrals would have resulted Under the assumption mentioned above 32 of these might have been justified and 16 unnecessary

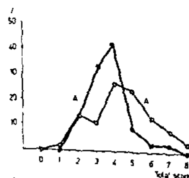

Fig 2 Referred children Percentual distribution of subgroups A_T (in need of treatment open circles) and A_H (healthy closed circles) with respect to total score at screening

3 *The discriminating power of the four screening instruments*

In Table 2 subgroups A_T and A_H are compared with respect to the relative proportions of children with scores 0 1 and 2 in each of the four sets of data A significant difference (tested by means of χ^2) is evident only for the interview score A similar though not significant tendency is noted with respect to the questionnaire and the direct examination score whereas the physician's final rating does not discriminate at all

The interview's discriminating power could be utilized in the following way If—in addition to those already screened out by the total score criterion—all children with an interview score of 2 had been referred to a specialist an additional 45 children probably needing treatment would have been assessed but at the same time the specialist team would have had to examine another 22 healthy children

If combined the criteria discussed in paragraphs 2 and 3 would have given an increase in the rate of correct referrals (children really in

Table I *Definition of scores 0 1 and 2 in the four screening instruments*

Instrument	Score 0	1	2
Questionnaire	No problems according to the parents	Somewhat late in devel opment and/or mild behaviour problems and/ or latent need of help	Retarded development and/or severe behaviour problems and/or mani fest need of help
Interview (sum of 27 items each item being coded 0 1 or 2)	0–3	4–9	10+
Examination/observation (sum of 5 items each item being coded 0 1 or 2)	0	1–5	6+
Physician s final rating	Normal for age	Somewhat deviant	Definitely deviant

the screening procedure was based on four different sources of data

(1) A simple questionnaire completed by the parents
(2) an interview conducted by the responsible nurse
(3) an examination of the child s development and di rect observation of his behavior and
(4) an overall rating by the physician

Each source of data yielded a varying number of items In order to simplify the analysis the entire information from each method was reduced to a single score in the scale 0 1 2 according to the criteria shown in Table I The sum of the four scores will be called the total score

As a result of the clinical assessment each referred child was assigned to one of three categories healthy child at risk and definitely deviant An additional classification was made in the group of referred children according to the *main symptom* aggressiveness anxiety infantile symptoms (enuresis encopresis thumb suck ing) restlessness/tension (hyperactivity sleep disturb ance problems of contact tics nail biting) The assign ment to one of these classes was based on the number and the severity of the individual symptoms within each cate gory as well as on the general prognostic significance of the symptoms (determined by common agreement of a group of child psychiatrists (4))

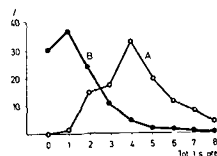

Fig I Percentual distribution of referred (open circles) and non referred (closed circles) children with respect to total score

MATERIAL

The present analysis is based on data concerning the chil dren examined in 1969 and 1970 Of the 3 897 invited chil dren 3 810 participated in the screening (=97 7%) For the present purpose only those with complete primary data are included The numbers may therefore vary some what between the different analyses depending on the variable(s) under study

Group A Children referred to the special assessment unit Originally this group comprised 158 children but only 127 of these were eventually seen by a specialist (5)

Subgroup A_T Referred children considered to be in need of treatment (child at risk and definitely devi ant) $n=85$

Subgroup A_H Referred children declared healthy by the specialist $n=42$

Group B Non referred children with complete data $N=3\,008$

RESULTS AND DISCUSSION

1 *Total score in referred and non referred children*

In Fig 1 the distributions of the total score in groups *A* and *B* show a significant overlap This indicates that the decision as to whether or not a child should be referred to a specialist did not depend exclusively on the total number of problems symptoms or failures emerging in the test but rather on the result of an overall interpretation of the possible significance of these findings The details of this process are largely unknown but some special features may be elucidated from the available data

The following calculations were made under

Table 2 *Distribution of screening scores in referred children*
A_T=in need of treatment A_H=healthy

	A_H n=40	37 5	35 0	27 5	

the assumption that if additional children had been referred to the specialists because their data fulfilled certain criteria they would have been assigned to subgroups A_T and A_H in the same proportions as those children who had been referred in reality The observation (5) that a group of preschool children referred to the specialist team through mechanisms other than screening was composed of healthy at risk and deviant children in proportions equal to those of group A shows that this assumption is probably realistic

2 *Total score in subgroups A_H and A_T*

Fig 2 depicts a considerable overlap This is an important finding because it indicates that the total score alone is not a very useful measure for the precise identification of children who will eventually need treatment In the region of score 5 or more however the discrimination appears satisfactory Thus if all children who had accumulated scores of 5 to 8 had been included another 48 referrals would have resulted Under the assumption mentioned above 32 of these might have been justified and 16 unnecessary

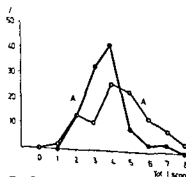

Fig 2 Referred children Percentual distribution of subgroups A_T (in need of treatment open circles) and A_H (healthy closed circles) with respect to total score at screening

3 *The discriminating power of the four screening instruments*

In Table 2 subgroups A_T and A_H are compared with respect to the relative proportions of children with scores 0 1 and 2 in each of the four sets of data A significant difference (tested by means of χ^2) is evident only for the interview score A similar though not significant tendency is noted with respect to the questionnaire and the direct examination score whereas the physician s final rating does not discriminate at all

The interview s discriminating power could be utilized in the following way If—in addition to those already screened out by the total score criterion—all children with an interview score of 2 had been referred to a specialist an additional 45 children probably needing treatment would have been assessed but at the same time the specialist team would have had to examine another 22 healthy children

If combined the criteria discussed in paragraphs 2 and 3 would have given an increase in the rate of correct referrals (children really in

Table 1 *Definition of scores 0 1 and 2 in the four screening instruments*

Instrument	Score 0	1	2
Questionnaire	No problems according to the parents	Somewhat late in development and/or mild behaviour problems and/or latent need of help	Retarded development and/or severe behaviour problems and/or manifest need of help
Interview (sum of 27 items each item being coded 0 1 or 2)	0–3	4–9	10+
Examination/observation (sum of 5 items each item being coded 0 1 or 2)	0	1–5	6+
Physician s final rating	Normal for age	Somewhat deviant	Definitely deviant

the screening procedure was based on four different sources of data

(1) A simple questionnaire completed by the parents
(2) an interview conducted by the responsible nurse
(3) an examination of the child s development and direct observation of his behavior and
(4) an overall rating by the physician

Each source of data yielded a varying number of items In order to simplify the analysis the entire information from each method was reduced to a single score in the scale 0 1 2 according to the criteria shown in Table 1 The sum of the four scores will be called the total score

As a result of the clinical assessment each referred child was assigned to one of three categories healthy child at risk and definitely deviant An additional classification was made in the group of referred children according to the *main symptom* aggressiveness anxiety infantile symptoms (enuresis encopresis thumb sucking) restlessness/tension (hyperactivity sleep disturbance problems of contact tics nail-biting) The assignment to one of these classes was based on the number and the severity of the individual symptoms within each category as well as on the general prognostic significance of the symptoms (determined by common agreement of a group of child psychiatrists (4))

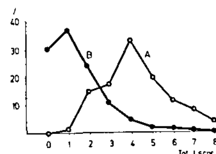

Fig 1 Percentual distribution of referred (open circles) and non referred (closed circles) children with respect to total score

MATERIAL

The present analysis is based on data concerning the children examined in 1969 and 1970 Of the 3 897 invited children 3 810 participated in the screening (=97 7%) For the present purpose only those with complete primary data are included The numbers may therefore vary somewhat between the different analyses depending on the variable(s) under study

Group A Children referred to the special assessment unit Originally this group comprised 158 children but only 127 of these were eventually seen by a specialist (5)

Subgroup A_T Referred children considered to be in need of treatment (child at risk and definitely deviant) $n=85$

Subgroup A_H Referred children declared healthy by the specialist $n=42$

Group B Non referred children with complete data $N=3008$

RESULTS AND DISCUSSION

1 *Total score in referred and non referred children*

In Fig 1 the distributions of the total score in groups *A* and *B* show a significant overlap This indicates that the decision as to whether or not a child should be referred to a specialist did not depend exclusively on the total number of problems symptoms or failures emerging in the test but rather on the result of an overall interpretation of the possible significance of these findings The details of this process are largely unknown but some special features may be elucidated from the available data

The following calculations were made under

Table 4 *Conducted interviews in per cent of participants and rate of referrals for psychological problems*

	1969	1970	Change of instructions ↓	1971
Conducted interviews %				
Rural districts	98	100		91
Urban districts	96	97		65
Rural+urban	96	98		77
Referrals %	5 4	3 7		5 0

whereas the simple developmental examination could be performed rapidly The observation of the child s behaviour was also an inexpensive method since it was made at the same time as the various examinations (physical and other) As a rule the completion of the questionnaire did not demand the participation of a professional

We therefore determined that percentage of the finally referred children for whom the questionnaire indicated a severe or a slight problem to these were added children with scores of 2 or 1 in the direct observation and examination The corresponding percentages for the total population of screened children were also computed

The result presented in Fig 3 shows that a combination of the data obtained from the questionnaire and from the direct observation and examination of the child could have identified 97% of all children who were finally referred It seems as if the interview data were used primarily for a further differentiation among those in whom the other sources had already pointed to the existence of some problems This observation prompted a change in strategy at the end of the year 1970 Thus according to the new instructions the interview should be carried out only in those cases where the other data had revealed a problem and in all previously unknown children and all previously known problem children The reason why the interview was not abolished completely was the finding that this instrument had a high discriminating power between correct and unnecessary referrals (see p 291) Although it did not add very much to the overall sensitivity of the screening program it constituted an important means of assuring a sufficiently high specificity It was anticipated that about 1/2 to 2/3 of the time spent on interviews could be saved by this strategy (Fig 3)

Table 4 shows what happened in reality the nurses especially those in the rural districts continued to conduct the interviews in the majority of cases probably because they had learned to regard this instrument as a means of establishing contact with the families in their district Nevertheless there was a significant decrease in the overall rate of conducted interviews As expected this decrease did not affect the rate of referrals for psychological problems Further the positive predictive value of the screening process remained essentially unchanged (71% as opposed to 67% in 1969 and 1970)

CONCLUSIONS

This analysis has shown that the screening procedure can be rationalized by a differentiated application of the various instruments without reducing the effectiveness The sensitivity which is the most important parameter of effectiveness could be improved considerably if all children with an overall interview score of 2, those with a total score of 5 or more and those with a heavy symptom load in the restlessness/tension complex were referred for specialist examination The anticipated gain in sensitivity (increase of correct referrals from 2 8 to 4 8% of all children) is probably a conservative estimate since it is based on the assumption that the proportion of false positives among the additional referrals would be the same as in those referred for the usual reasons As a matter of fact the additional referral criteria proposed here were chosen just because of their especially high discriminating power and the proportion of

Table 3 *Distribution of referred children with respect to main symptoms*

Main symptom	Classification by the specialist			
	Healthy (n=42)		Definitely deviant (n=27)	
	No	%	No	%
Aggressiveness	7	17	3	11
Anxiety	19	45	5	19
Infantile behaviour	4	10	1	4
Restlessness/ tension	7	17	18	67
No symptoms	5	12	0	0

need of treatment) from 2 8 to 4 8% of the total population or from 2 2 to 3 8% if allowance is made for those 20% of the referred who would refrain from the proposed special consultation This theoretical result could have been achieved without any change in the screening procedure but probably at the cost of specialist examinations of another 30 healthy children

4 *Qualitative aspects of the criteria for referral*

The percentual distribution of the children in group *A* with respect to the main symptoms is shown in Table 3 There is a significant difference between subgroups A_H and A_T the children needing treatment presenting more often with symptoms within the class restlessness/ tension whereas anxiety dominated as the main symptom in those declared to be healthy A similar classification was made in groups *A* and *B* on the basis of the symptoms elicited in the screening interview

No significant difference was found between the two groups with respect to the pattern of symptoms though of course all the symptoms occurred more frequently in group *A* This probably indicates that the decision for referral was not based on the qualitative aspects—at least not in a systematic manner In view of the specialists more serious rating of the restlessness/tension complex however these symptoms should be given particular weight as a referral criterion

5 *Improving the cost efficiency*

The systematic application of the criteria mentioned in paragraphs 2 3 and 4 might be expected to improve the effectiveness of the screening process The costs of the screening would remain unchanged but the work load at the assessment unit would increase significantly Therefore this modification of the strategy would probably not change the overall cost efficiency ratio Since the total cost is an important issue in view of the limited resources available attempts were made early in the process of program evaluation to diminish the costs without changing the effectiveness (8)

The most expensive item in terms of manpower was the interview with the parents

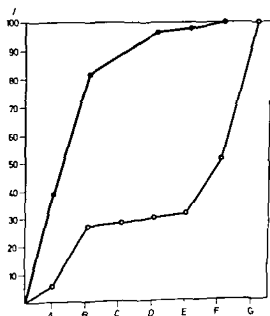

Fig 3 Cumulative percentage of children in referred group (closed circles) and in total material (open circles) with scores of 2 and 1 in questionnaire examination/observation and in interview Instruments ordered according to their relative costs (inexpensive→expensive)

false positive might therefore be even lower The implementation of these criteria would imply more clerical work for the staff since the scores have to be computed from a number of items Therefore if an automatic monitoring system is available (7) these criteria could be built in so that those cases who were not referred in spite of fulfilment of the criteria would be revealed and discussed after the screening

If the present procedure of performing the interview only in selected cases is retained the possible gain in sensitivity will be somewhat lower than the theoretical figure anticipated in paragraph 3 but it may still be expected to be substantial

The conclusions in this article rely heavily on the validity of the specialists evaluation of the referred children s need of treatment The relatively serious prognosis attached to the hyperactivity syndrome is in accordance with published experience (2 6) but as yet we do not know whether the problems of those children who have been declared healthy really were trivial and self limiting Furthermore certain deviating behaviours though troublesome for parents and others may very well be helpful for the child himself We believe however that it is important to identify not only disturbed children but also those parents who need help in order to arrive at a true understanding of their troublesome child The emphasis on the child s symptoms during the screening appears to be the most effective way to enable parents to engage in a discussion with specialists concerning their attitude towards the child We are not able to prove however that this aim has been achieved A systematic follow up now in progress may provide an answer to this and other questions raised in this paragraph

Systematic screening of preschool children for psychological problems is a relatively new enterprise and there are very few reports with which our results can be compared Prevalence rates from epidemiological studies without therapeutic intervention (1 3) should be compared with frequencies of symptoms or of combined scores as revealed by our screening instruments rather than with the percentage of children finally receiving some treatment In our view, however, this latter figure is the only relevant one if we accept the assumption that the treatment has a beneficial influence on the future development of the child At the present time no reliable data are available concerning the number of children who might really profit from some sort of intervention The true figure may be very much higher than the few per cent found in our investigation In view of the many uncertainties in this field however it would appear wise to study the experience gained from a restricted group before any drastic expansion of the resources for intervention is considered

In this context it is necessary to point out that some counselling was also provided for the non referred children at the Child Health Centers Unfortunately we have no quantitative data on this unsophisticated therapeutic activity but we know from personal experience that it represented a positive complement to the referral routines especially for those parents who hesitated to consult a psychologist or a psychiatrist We believe in fact that an optimal model for preventive action will have to integrate a number of activities guided by laymen as well as by professionals of different levels of formal competence and from various specialties Screening and subsequent treatment by specialists represents one important part of a comprehensive program and it may very well serve as a starting point for further developments

PHYSICAL HEALTH OF 7 YEAR OLD CHILDREN

An Epidemiological Study of School Entrants and a Comparison with Their Preschool Health

LENNART KÖHLER

From the Department of Paediatrics University Hospital Lund and Dalby Community Health Research Centre Dalby Sweden

ABSTRACT Kohler L (Department of Paediatrics University Hospital Lund and Dalby Community Health Research Centre Dalby Sweden) Physical health of 7 year-old children An epidemiological study of school entrants and a comparison with preschool health Acta Paediatr Scand 66 297 1977.—At 7 years of age all 649 7 year-old children in a school district underwent a physical examination a vision screening and an auditory screening 210 of the children were previously examined in an extensive health control at 4 years of age The purpose of the present study was to describe the children s health situation and to evaluate the special health control performed at 4 years of age In 15% of the children functionally important health problems were found Visual defects were most common comprising 7.5% then came physical health problems such as motor disturbances obesity bacteriuria in 6 5% and hearing defects in 1% About half of the important health problems were previously known Children who had passed the special health control at 4 years of age had fewer newly detected important health problems and more previously known ones than other children which means that many children with above all visual defects but also motor disturbances bacteriuria and testis retention were detected and treated earlier than would have happened without the special control at 4 years It is concluded that the ordinary preschool Child Health Services did fulfill their purpose to detect handicapping disorders in an acceptable way by the introduction of the special health control at 4 years of age this function was further improved

KEY WORDS School health vision screening hearing screening obesity

The aim of the school health programme is to keep and increase the children s physical and mental health and to prevent and detect disease and handicap The modern school with long compulsory education and new curricula has also influenced the extense and intension of school health services Thus to the physical health examination formerly the one and only form of health surveillance have been added aspects of the children s mental health and social welfare this means that several new groups of personnel have been included in the health service beside physicians and nurses e g psychologists and social workers However the doctor and his physical examinations still play an important role in the school health programme

One of the purposes with the present study was to describe in school entrants the frequency and types of physical disabilities that might influence the present and future function of the child

Another purpose was to evaluate a special health control of four year-old children which was introduced some years earlier (14) Already at the planning of this examination of preschool children it was decided that it should be repeated when the children began school at the age of seven In addition another group of 7 year-old children who had not been

% of the girls
* of the boys

A level of 20 dB ISO was considered normal except at the lower frequences (250 and 500 cps) where 25 dB was accepted because of the unavoidable enviromental noise in the testing room

Children with hearing impairment at [illegible] or more frequences on the same ear were referred to the audiologist for further evaluation According to this professional evaluation a classification of the hearing impairments was made (Table 1)

Children with health problems considered to be functionally important at the present or in the future and not under current professional care were referred for further evaluation via the ordinary school physician After evaluation and diagnosis the health problems were graded according to their importance for the children s health and development (13 14) (Table 1)

Groups 2 and 3 were considered as *functionally important health problems* corresponding to the same definition at the health control of 4-year-olds (11 12 13 14) *Previously known* means that the health problems had already been detected and cared for before the actual investigation

RESULTS

Deviations revealed in the physical examination are presented in Table 2 Functionally important health problems in these children at 4 years of age are also shown

Motor disturbances dominate the picture just as they did at 4 years of age In category not 4 2 3% and in category 4 6 2% had motor disturbances The majority though showed only slight deviations i e immature clumsy gross or fine movements or slight tremor The difference of frequency between the two categories is not statistically significant ($p>0.05$) The more serious deviations (groups 2 and 3) concerned a boy with an operated hydrocephalus a boy with an operated cerebellar tumour 2 boys and 1 girl with brain damage and epilepsy and 3 children with pronounced motor difficulties combined with hyperactivity and short attention span (minimal brain dysfunction MBD) Seven of these children were previously known and treated Sixteen children were investigated when they were 4 years old only 3 had then functionally important deviations (the boy with hydrocephalus and 2 boys with MBD)

Overweight was also frequent in 59 children (9 1%) the weight was 2 S D above their standard weight for height and in 25 children

Table 1 *Classification of health problems*

Method of examination	Group 0 Healthy child	Group 1 Slight deviation without importance	*Group 2* Moderate deviation *Treatment indicated*	*Group 3* Definitely handicapping disorder
General physical examination		Flat feet phimosis	Retentio testis MBD obesity	Cerebral palsy organic heart disease
Vision examination		*Myopia*<−*1* 0 D Hyperopia<+1 5 D Astigmatism<±1 5 D *Slight* heterophoria	Refractive errors without amblyopia Heterophoria with complaints	Amblyopia strabismus
Auditory examination		Mild otosalpingitis cured by simple otological measures and few visits to the physician	Protracted otosalpingitis requiring more intense therapy (adenoidectomy drainage tubes) Moderate sensorineural hearing impairments with need for follow up and control	Severe impairment requiring hearing aid or special education

investigated in this way earlier were examined Thus it should be possible to compare the physical health of a group of 7 year old children with the health of the same children at 4 years of age as well as with another group of 7 year old children who had not passed the special health control at the age of 4 years

MATERIAL

In the first class at the age of 7 years 649 children born 1962–1965 and living in the school district of Dalby in Southern Sweden were examined

The school district is congruent with the medical district where the special health examinations of 4 year-old children were performed in 1968–1969 (14) Out of the 649 school entrants 210 were examined as preschool children (called category 4) and 439 were not examined as preschool children (called category not 4)

METHODS

General physical examination

The physical examination consisted of a somewhat extended class examination according to a structured and standardised form It was performed in the schools by the author assisted by a registered nurse By a careful inspection and palpation of the undressed child abnormalities of the mouth throat superficial lymph nodes thyroid gland skin skeleton muscles and abdomen were recorded In boys the testes and the foreskin were examined Heart and lungs were auscultated pulsations of the femoral arteries were palpated

Posture and spontaneous motor behaviour were observed with the child sitting standing walking and running Attention was paid to asymmetry in stature and movements and also to the presence of involuntary movements Further observation of the gross movements and coordination was made while the child was walking along a straight line walking on tiptoe and on the heels and standing or hopping on one leg Fine movements and coordination were studied while the child was cutting a piece of paper with a pair of scissors and was threading small wooden beads on a string

Inappropriate activity and disordered attention span in a child during the examination were also recorded e g constantly moving around touching and handling objects without discernible purpose Screening for bacteriuria was performed by a test paper Uriglox* which in previous studies in preschool and school children was found to be very reliable (24) Height and weight were measured with the school s standard equipment a scale on the wall with a wooden headpiece and a platform balance Weight for height was calculated on a standard curve for Swedish children (2)

Vision examination

The monocular visual acuity was tested by the school nurse with a linear E-chart (Oculus) at a distance of 5 meters Children with a visual acuity of 0 9 or less on one or both eyes were referred to the ophthalmologist for further evaluation (12) After the professional examination the visual deviations were classified according to their impact on the children s health and function and on the need for care (Table 1)

Auditory examination

The auditory examination was performed in the schools by a specially trained nurse using an audiometer (Tegnér PTA 9) with double earphones The testing was made at 250 500 1000 2000 4000 an

category not 4 (1.9%) and in no one in category 4

Bacteriuria was revealed in 0.9% of the girls 1.4% in category not 4 and not at all in category 4 The difference in frequency between the two groups is not statistically significant ($p>0.05$) None of the children had bacteriuria at 4 years of age either No boy had bacteriuria

Altogether 42 seven year-old children entering school (6.5%) were considered to have functionally important physical health problems 27 (6.1%) in category not 4 and 15 (7.1%) in category 4 The difference between the two categories is not statistically significant ($p>0.05$)

Hearing

The frequency and kind of hearing impairments are shown in Table 5 Of the referred children 4.5% in category not 4 and 3.8% in category 4 ($p>0.05$) almost half had normal hearing when examined by the audiologist and about 1/3 had otosalpingitis Sensorineural hearing impairments were rare and the important ones had already been taken care of All children found to have otosalpingitis at 7 years of age were healthy at 4 years

Two children with slight sensorineural defects at 7 years had normal hearing at 4 years of age Three children with newly detected important impairment had all protracted middle ear infections

Vision

The distribution of visual disturbances is shown in Table 4 Significant eye disorders (groups 2 and 3) were found in 5.7% in category not 4 and in 11.4% in category 4 The difference is significant ($p<0.05$) Also the existence of previously known significant eye disorders was more common in category 4 ($p<0.001$) Newly discovered significant eye disorders were found in 3.9% and 2.4% respectively ($p>0.05$) (Table 6)

A comparison with the health control at 4 years of age shows that 24 of the school en

Table 3 *Weight for height in 210 children at 4 and 7 years of age*

Weight for height at 4 years	Weight for height at 7 years M+3 S D	M+2 S D	<M+2 S D	Sum
M+3 S D	(*a*) 3	(*b*) 1	(*c*) 0	(*d*) 4
M+2 S D	(*e*) 2	(*f*) 3	(*g*) 4	(*h*) 9
<M+2 S D	(*i*) 5	(*k*) 5	(*l*) 187	(*m*) 197
Sum	(*n*) 10	(*o*) 9	(*p*) 191	(*r*) 210

Limit +3 S D
Sensitivity $(a/n)\times 100=33\%$
Specificity $(f+g+k+l)/(o+p)\times 100=99\ 5\%$
Positive predictive value $(a/d)\times 100=75\%$

Limit +2 S D
Sensitivity $(a+b+e+f)/(n+o)\times 100=47\%$
Specificity $(l/p)\times 100=98\%$
Positive predictive value $(a+b+e+f)/(d+h)\times 100=69\%$

(3 9%), 12 girls and 13 boys the weight exceeded+3 S D (obesity) (Table 2) Ten of these 25 obese children were examined at 4 years of age Their mean weight at that time was 22 4 kg which is more than the mean weight for all 4 year olds (17 2 kg $p<0\ 001$) In three of them the weight for height exceeded+3 S D and was already at that time considered as a functionally important health problem Dietary treatment had been instituted and was continued sporadically but without great success

Out of the remaining children who had at 7 years a weight for height exceeding the standard with 2 S D 9 were examined at 4 years of age 3 were then at+2 S D and 1 above+1 S D In category not 4 8 children were reported to have been treated for obesity before school began also without success

Table 3 where the relation between weight and height at 7 years is compared with the same relation at 4 years of age can be used to compute the possibilities to predict at 4 years of age the risk of overweight at 7 years of age If +3 S D is used as the lower limit of obesity the sensitivity of the measurement will be 33% and the specificity 99 5% i e one third of the children who are obese at 7 years were obese already at 4 years and only one out of 200 7 year olds with normal weight was overweight at 4 years The predictive value of measurement is 75% i e 3 out of 4 children who were obese at 4 years will also be obese at 7 years If the limit of overweight is instead drawn at +2 S D the sensitivity will be 47% the specificity 98% and the predictive value 69%

Retentio testis was found in 3 of the boys in

tation inside and outside school but also what possibilities for care and alleviation can be offered by the society This means that in our country with its excellent economic social and medical resources heavy demands on optimal health could be made and thus that many deviations could be regarded as important to detect and treat

The deviations counted as important are listed in detail in Tables 1 and 4 and described in the classifications under *methods* The diagnoses and the classifications have been adapted as closely as possible to these used in the health control of 4 year old children (11 12 13 14)

The general health of the children was very good and severely handicapping disorders were detected and cared for already before school Slight motor disturbances with clumsiness and unskillfulness in performing the motor tests were rather common but were mostly regarded as normal variations Only in exceptional cases were they considered as important for the child s health and adaptation None of the 13 children with such a slight motor deviation had functionally important motor disturbances at 4 years of age In 3 children this clumsiness was combined with excessive mobility restlessness short attention span and hyperactivity i e what is usually called minimal brain dysfunction MBD

A closer penetration of these MBD-children and their behaviour at home and in school is necessary to be able to evaluate their special need for medical and educational support and help A follow up of a larger material of MBD-children is in progress

The frequency of *retentio testis* (3/223) in category not 4 does not differ significantly from that found in the health control of 4 year-olds (12/1972) (13) In category 4 no boy with testicular retention was found and with regard to the risk of infertility and malignancy it would have been more favourable for the 3 boys in category not 4 if their retentio testis had been detected and treated already in preschool age (17)

Bacteriuria was as frequent as in other studies of this age group—about 1% (10 14 23 24) Also as usual no boys with bacteriuria were discovered

Obesity in children is usually recognised as a precursor of obesity in adults which has evident negative effects on morbidity and mortality (18) An early identification of children at risk may therefore be important Several studies (1 5 6) indicate that rapid weight gain in infancy may be connected with obesity later in childhood However recent data from Swedish children do not confirm these findings (19) The actual frequencies of overweight defined as 2 S D above mean weight for height (9 1%) and obesity defined as 3 S D above mean weight for height (3 9%) are somewhat higher than in other studies of the same age groups of children (9 22) The increasing frequency of overweight from preschool age to school age is well known (18 20) as is also the fact that there is a tendency for obesity to persist from infancy throughout the preschool and school years (1 6 18)

However the possibility to predict with accuracy in preschool age who will be obese in school seems to be limited Thus only 1/3 of the obese school entrants were obese at 4 years of age and hardly any of the overweight ones were overweight at 4 years Besides still almost 20% of the overweight 4 year old children had normal weight at 7 years

The time for follow up is of course too short and the number of children in the study too small to allow definite conclusions to be drawn about riskgroups of obesity in childhood However it is evident that overweight is frequent in school children and that the number of overweight children increases during the later part of the preschool years Apparently measures for treatment and prevention have not been sufficient

In total 15 0% of the school entrants had functionally important health problems which is well in accordance with the findings in the preschool age (15 0%) and with the statement that the prevalence of chronic conditions in

trants with significant eye disorders had been examined earlier and that 3 of them had a normal visual screening test at that time All these 3 children were now at 7 years amblyopic in one eye one boy had a pronounced corneal astigmatism one had hyperopia and an excentric fixation and one had an eye muscle paresis It is very likely that these deviations did exist already at 4 years of age although they were not detected at the screening

Another 2 children had slight refractive errors at 4 years (astigmatism) and had not been considered in need of treatment at that time (group 1) In school however the demand for visual acuity is greater and they received glasses (group 2) Further on 3 children with significant eye disorders at 4 years (hyperopia astigmatism) had normal visual acuity at 7 years evidently a result of treatment An analysis of treated eye disorders in a greater number of school children is under preparation

In summary 15% of the 649 children entering school were found to have important health problems by either of the three methods of investigation—physical examination vision screening and hearing screening (Table 6) Visual defects were responsible for the largest part 7 5% while hearing defects were most infrequent 1% About half of the important health problems (51 5%) were previously known

Of the 210 children examined both at 4 and 7 years 42 (20%) had functionally important health problems at 7 years (Table 6) Two thirds of these defects were discovered already at the health examination at 4 years of age and were being treated and controlled The 14 newly detected children include 7 with obesity 2 with middle ear infection and 5 with visual defects Two of the children with visual defects were previously diagnosed as belonging to group 1 i e treatment was probably not necessary until school began

A pervading characteristic of Table 6 is that children who have passed the health control at 4 years of age have fewer newly detected important health problems and more previously known ones than other children This difference is most marked regarding previously known eye disorders

DISCUSSION

It can always be questioned which deviations from health should be considered as important for the child In this consideration it must be taken into account not only what influence the deviation may have on the child and his adap

tation inside and outside school but also what possibilities for care and alleviation can be offered by the society This means that in our country with its excellent economic social and medical resources heavy demands on optimal health could be made and thus that many deviations could be regarded as important to detect and treat

The deviations counted as important are listed in detail in Tables 1 and 4 and described in the classifications under *methods* The diagnoses and the classifications have been adapted as closely as possible to these used in the health control of 4 year old children (11 12 13 14)

The general health of the children was very good and severely handicapping disorders were detected and cared for already before school Slight motor disturbances with clumsiness and unskillfulness in performing the motor tests were rather common but were mostly regarded as normal variations Only in exceptional cases were they considered as important for the child s health and adaptation None of the 13 children with such a slight motor deviation had functionally important motor disturbances at 4 years of age In 3 children this clumsiness was combined with excessive mobility restlessness short attention span and hyperactivity i e what is usually called minimal brain dysfunction MBD

A closer penetration of these MBD-children and their behaviour at home and in school is necessary to be able to evaluate their special need for medical and educational support and help A follow up of a larger material of MBD-children is in progress

The frequency of *retentio testis* (3/223) in category not 4 does not differ significantly from that found in the health control of 4 year-olds (12/1972) (13) In category 4 no boy with testicular retention was found and with regard to the risk of infertility and malignancy it would have been more favourable for the 3 boys in category not 4 if their retentio testis had been detected and treated already in preschool age (17)

Bacteriuria was as frequent as in other studies of this age group—about 1% (10 14 23 24) Also as usual no boys with bacteriuria were discovered

Obesity in children is usually recognised as a precursor of obesity in adults which has evident negative effects on morbidity and mortality (18) An early identification of children at risk may therefore be important Several studies (1 5 6) indicate that rapid weight gain in infancy may be connected with obesity later in childhood However recent data from Swedish children do not confirm these findings (19) The actual frequencies of overweight defined as 2 S D above mean weight for height (9 1%) and obesity defined as 3 S D above mean weight for height (3 9%) are somewhat higher than in other studies of the same age groups of children (9 22) The increasing frequency of overweight from preschool age to school age is well known (18 20) as is also the fact that there is a tendency for obesity to persist from infancy throughout the preschool and school years (1 6 18)

However the possibility to predict with accuracy in preschool age who will be obese in school seems to be limited Thus only 1/3 of the obese school entrants were obese at 4 years of age and hardly any of the overweight ones were overweight at 4 years Besides still almost 20% of the overweight 4 year old children had normal weight at 7 years

The time for follow up is of course too short and the number of children in the study too small to allow definite conclusions to be drawn about riskgroups of obesity in childhood However it is evident that overweight is frequent in school children and that the number of overweight children increases during the later part of the preschool years Apparently measures for treatment and prevention have not been sufficient

In total 15 0% of the school entrants had functionally important health problems which is well in accordance with the findings in the preschool age (15 0%) and with the statement that the prevalence of chronic conditions in

most populations under 20 lies between 10% and 15% (14, 21) Visual defects dominate and hearing impairments are most uncommon as was also the case among children 4 years of age

The aim of the Child Health Services is to provide all children from birth to school age with a complete health surveillance To in crease the possibilities to fulfil this aim a gen eral health control of all 4 year old children was introduced in Sweden in 1969 (7 14) promoted by the handicap organisations Re sults from this health control in different parts of the country have shown unanimously that the health of preschool children is very good and that the majority of the seriously handi capping disorders are detected and treated already before 4 years of age although certain areas of the health surveillance are neglected *e g* dental health, vision hearing behaviour and upbringing (9, 14 15 24, 25 26)

With this background it is not probable that a follow up examination at 7 years of age would reveal large unknown defects of children s health Nevertheless, it would be of great interest to repeat the examination after 3–4 years and to let it serve as an evaluation of the efficiency of earlier examination It would be possible to find out whether a newly de tected health problem really was newly de veloped or had existed before but not been discovered The tendency to find fewer newly detected important health problems and more previously known ones in children who had been examined at 4 years of age compared with those who were not is an indication of the diagnostic capacity of the health control of 4 year olds Children with visual defects motor disturbances bacteriuria and testis re tention were detected and treated earlier than otherwise would have been the case On the other hand, the difference between the two categories was not very great and it is evident that also the ordinary health surveillance of preschool children has fulfilled its purpose in an acceptable way The greatest difference be tween the two categories was found among the visual defects naturally enough since visual defects in this age seldom are detected unless the visual acuity is examined In fact, 2 of the 5 children with newly detected visual defects had already been diagnosed at 4 years as de fects perhaps necessary to treat in school but not before

Nevertheless 3 children with amblyopia in one eye were missed when screened at 4 years The exact cause of these failures are not known—it might be a defective covering of the non tested eye—but it is evident that a certain under referral (as well as a certain over refer ral) is inevitable in screening procedures However the results have led to a check on the screening methods

The other previously examined children with newly detected functionally important health problems, had deviations that un doubtedly developed between 4 and 7 years of age (obesity and middle ear infections) Thus Child Health Services have fulfilled their func tion to detect handicapping disorders in pre school children By the introduction of the special health control at 4 years of age this function is further improved However also after the age of 4 years deviations occur that are important to detect and treat early and this means that the health surveillance should continue and be repeated also during the later part of the preschool period

PHYSICAL MASS EXAMINATIONS IN THE SCHOOL HEALTH SERVICE

LENNART KÖHLER

From the Department of Paediatrics University Hospital Lund and Dalby Community Health Research Centre Dalby Sweden

ABSTRACT Köhler L. (Department of Paediatrics University Hospital Lund and Dalby Community Health Research Centre Dalby Sweden) Physical mass examination in the school health service Acta Paediatr Scand 66 307 1977.—At 7 years of age all 649 children in a school district underwent a physical examination a vision screening and an auditory screening The purpose of the present study was to analyse the value of the routine physical examination within the school health services In 15% of the children functionally important health problems were found Visual defects were most common comprising 7 5% then came physical health problems such as motor disturbances obesity bacteriuria in 6 5% and hearing defects in 1% About half of the important health problems were previously known Most disorders of importance were detected by the nurse s screening examination and rather few by the doctor s physical examination It seems advisable to introduce screening procedures in the hands of nurses also for the physical examination The role of the school physician in the general health surveillance would then be mainly to control and verify specific observations or suspicions of disease or handicap noted by the school nurse His time and attention could instead be directed towards important tasks which are now often neglected e g health education and care of sick and handicapped children in the school setting

KEY WORDS School health screening examinations

Health examination of school-children is one of the few compulsory health examinations in Sweden According to regulations routine physical examinations should be performed on all children in certain classes usually 1 4 7 and 9 i e at 7 10 13 and 15 years of age Besides special consultations should be arranged by the school physician and/or the school nurse for children in need of such contacts

Although other aspects of the children s health and welfare have been added a great part of the doctor s time is still taken up by routine physical examinations However the value of such periodic medical inspections is not properly documented Studies mostly from England and USA (1 7 8 9 10 11) give an almost depressing picture of the efficiency and usefulness of such examinations In Sweden practically no efforts have been made to evaluate what is achieved in the school health services A recent small study from Uppsala concludes that the results of the clinical examination of children when they enter school are very sparse and a restriction of this item is recommended (2)

The purpose of the present paper is to discuss the aims and methods of the school health service as they were elucidated in an epidemiological study of the physical health of 7 year old entrants (5)

MATERIAL AND METHODS

In the first class at the age of 7 years 649 children born 1967–1965 and living in the school district of Dalby in Southern Sweden were examined

screening examinations of vision hearing urine weight and height (43 children or 6 7%) Also the physician discovered some new im portant deviations but they were rather few (4 children or 0 6% 3 boys with retentio testis and 1 with minimal brain dysfunction)

DISCUSSION

Medical care of children in the school setting is provided in routine class examinations in consultations and in case conferences and is mainly directed towards prevention Consulta tions and conferences are meant for children with special health problems and also for children at risk while the early discovery of disease and handicap is concentrated mainly on the regular routine mass examinations usually at 7 10 13 and 15 years of age These examinations include questionnaires about previous and actual diseases measuring of weight and height and a somatic check up by the physician Besides the school nurse screens for abnormalities of vision hearing and urine

The present study may be regarded as one of these routine health examinations Since the study comprised the total number of 7 year-old children in the area and since all children were examined by the same staff who used standardised methods and uniform classifications it is possible to make a reliable evaluation of the results

It is evident that the yield from the physi cian s examinations was not very high and it is also clear that the methods used by the physi cian were time consuming and expensive (clinical examination)

Of course there are other aspects of routine check ups that may make them valuable for doctors parents and children e g the op portunities of establishing a positive first con tact for the benefit of future cooperation

These more subtle considerations of health care are also important and they could be pro vided for e g by conferences meetings les sons and demonstrations However it does not seem appropriate to devote that much time and money to medical performances with so low a yield and to detect among healthy children deviations in need of medical evalua tion and treatment there are other and better methods than the traditional clinical examina tion

Screening methods can be used more exten sively also here e g by letting the nurse make a short physical appraisal according to standardised questionnaires and observation forms (1 3 6) Based on these observations the school physician performs an assessment on selected children and the clinical examina tion then serves as a purposeful diagnostic method Thus the school physician will sel dom or never use clinical examinations as screening methods to identify health prob lems but he will use them for assessment based on specific observations or suspicions of disease or handicap A reduction of the number of physical mass examinations will mean that more of the school physician s time and attention can be paid to important tasks which are now often neglected e g to health education of both teachers and pupils and to vocational guidance It could also mean that more time could be found for increased medi cal and co-ordinating responsibility within the school setting for children with chronic dis eases and handicaps and perhaps also for better possibilities to treat sick children

In this way school health services would provide health care that is more tailored to the needs of the individual than it is today

Table 1. *Classification of health problems*

Method of examination	Group 0 Healthy child	Group 1 Slight deviation without importance	Group 2 Moderate deviation. Treatment indicated	Group 3 Definitely handicapping disorder
General physical examination		*Flat feet*, phimosis	Retentio testis, MBD, obesity	Cerebral palsy, organic heart disease
Vision examination		*Myopia* <−1.0 D Hyperopia <+1.5 D *Astigmatism* <±1.5 D Slight heterophoria	Refractive errors without amblyopia. Heterophoria with complaints	Amblyopia, strabismus
Auditory examination		Mild otosalpingitis cured by simple otological measures and few visits to the physician	Protracted otosalpingitis requiring more intense therapy (adenoidectomy, drainage tubes). Moderate sensorineural hearing impairment with need for follow-up and control	Severe impairment requiring hearing aid or special education

According to a structured and standardised form the children's physical health was examined by the author. Screening of vision, hearing, urine and measurements of height and weight were performed by the school nurse. A more detailed description of the methods has been given previously (5). Children with health problems considered to be functionally important, at present or in the future and not under current professional care, were referred for further evaluation via the ordinary school physician. After evaluations and diagnosis, the health problems were graded according to their importance for the children's health and development (Table 1) (4).

Groups 2 and 3 were considered as *functionally important health problems* (5). *Previously known* means that the health problems had already been detected and cared for before the actual investigation.

Table 2. *Physical examination*

Sum of functionally important health problems (all in *b*, *c*, *d*, *e*, *f*, *g*, *l*)	42	6.5
Newly detected (in *b*, *d*, *e*, *g*)	22	3.4

RESULTS

Out of the 649 children entering school 15% were found to have important health problems by either of the three methods of investigation—physical examination, vision screening and hearing screening (Tables 2 and 3). Visual defects were responsible for the largest part, 7.5%, while hearing defects were most infrequent, 1%. About half of the important health problems (51.5%) were previously known. Details of the findings are given in a previous paper (5).

Most deviations of importance for the children's health were detected by the nurse's

screening examinations of vision hearing urine weight and height (43 children or 6 7%) Also the physician discovered some new important deviations but they were rather few (4 children or 0 6% 3 boys with retentio testis and 1 with minimal brain dysfunction)

DISCUSSION

Medical care of children in the school setting is provided in routine class examinations in consultations and in case conferences and is mainly directed towards prevention Consultations and conferences are meant for children with special health problems and also for children at risk while the early discovery of disease and handicap is concentrated mainly on the regular routine mass examinations usually at 7 10 13 and 15 years of age These examinations include questionnaires about previous and actual diseases measuring of weight and height and a somatic check up by the physician Besides the school nurse screens for abnormalities of vision hearing and urine

The present study may be regarded as one of these routine health examinations Since the study comprised the total number of 7 year-old children in the area and since all children were examined by the same staff who used standardised methods and uniform classifications it is possible to make a reliable evaluation of the results

It is evident that the yield from the physician s examinations was not very high and it is also clear that the methods used by the physician were time-consuming and expensive (clinical examination)

Of course there are other aspects of routine check ups that may make them valuable for doctors parents and children e g the opportunities of establishing a positive first contact for the benefit of future cooperation

These more subtle considerations of health care are also important and they could be provided for e g by conferences meetings lessons and demonstrations However it does not seem appropriate to devote that much time and money to medical performances with so low a yield and to detect among healthy children deviations in need of medical evaluation and treatment there are other and better methods than the traditional clinical examination

Screening methods can be used more extensively also here e g by letting the nurse make a short physical appraisal according to standardised questionnaires and observation forms (1 3 6) Based on these observations the school physician performs an assessment on selected children and the clinical examination then serves as a purposeful diagnostic method Thus the school physician will seldom or never use clinical examinations as screening methods to identify health problems but he will use them for assessment based on specific observations or suspicions of disease or handicap A reduction of the number of physical mass examinations will mean that more of the school physician s time and attention can be paid to important tasks which are now often neglected e g to health education of both teachers and pupils and to vocational guidance It could also mean that more time could be found for increased medical and co-ordinating responsibility within the school setting for children with chronic diseases and handicaps and perhaps also for better possibilities to treat sick children

In this way school health services would provide health care that is more tailored to the needs of the individual than it is today

Table 1 *Classification of health problems*

Method of examination	Group 0 Healthy child	Group 1 Slight deviation without importance	Group 2 Moderate deviation Treatment indicated	Group 3 Definitely handicapping disorder
General physical examination		Flat feet phimosis	Retentio testis MBD obesity	Cerebral palsy organic heart disease
Vision examination		*Myopia* <−1 0 D Hyperopia <+1 5 D Astigmatism <±1 5 D Slight heterophoria	Refractive errors without amblyopia Heterophoria with complaints	Amblyopia strabismus
Auditory examination		Mild otosalpingitis cured by simple otological measures and few visits to the physician	Protracted otosalpingitis requiring more intense therapy (adenoidectomy drainage tubes) Moderate sensorineural hearing impairment with need for follow up and control	Severe impairment requiring hearing aid or special education

According to a structured and standardised form the children s physical health was examined by the author Screening of vision hearing urine and measurements of height and weight were performed by the school nurse A more detailed description of the methods has been given previously (5) Children with health problems considered to be functionally important at present or in the future and not under current professional care were referred for further evaluation via the ordinary school physician After evaluations and diagnosis the health problems were graded according to their importance for the children s health and development (Table 1) (4)

Groups 2 and 3 were considered as *functionally important health problems* (5) *Previously known* means that *the health problems had already been detected and cared* for before the actual investigation

Table 2 *Physical examination*

Health problems	n=649 n	%
(*a*) Motor disturbance group 1	23	3.5

Sum of functionally important health problems (all in *b c d e f g l*)	42	6.5
Newly detected (in *b d e k*)	22	3.4

RESULTS

Out of the 649 children entering school 15% were found to have important health problems by *either of the three methods of investigation*—physical examination vision screening and hearing screening (Tables 2 and 3) Visual defects were responsible for the largest part 7.5% while hearing defects were most infrequent 1% About half of the important health problems (51.5%) were previously known *Details of the findings are given in a previous* paper (5)

Most deviations of importance for the children s health were detected by the nurse s

EXCESSIVE HEPATIC GLYCOGEN STORAGE IN GLUCOSEPHOSPHATE ISOMERASE DEFICIENCY

J P G M VAN BIERVLIET and G E J STAAL

From the University Children s Hospital Het Wilhelmina Kinderziekenhuis and the Unit of Medical Enzymology Academic Hospital of the Dutch State University Utrecht The Netherlands

ABSTRACT Van Biervliet J P G M and Staal G E J (University Children s Hospital Het Wilhelmina Kinderziekenhuis Utrecht The Netherlands) Excessive hepatic glycogen storage in glucosephosphate isomerase deficiency Acta Paediatr Scand 66 311 1977.—Excessive amounts of glycogen were found in liver and erythrocytes of a patient suffering from generalized glucosephosphate isomerase deficiency A low carbohydrate diet fre quent meals and avoidance of peak carbohydrate challenges resulted in a significant decrease of liver volume without affecting the haematological condition The possible mechanism of these findings are discussed

KEY WORDS Glucosephosphate isomerase deficiency glycogen storage

Glucosephosphate isomerase (GPI) (E C 5 3 1 9) catalyses the reversible interconver sion of glucose-6-phosphate (G 6 P) and fructose 6-phosphate (F 6-P) Human GPI has been shown to exist in several rare electro-phoretic forms and in at least 18 physico chemically different deficient variants (17) So far very little attention has been given to the effects of GPI deficiency on organ systems other than blood cells Evidence of excessive glycogen storage in liver tissue and erythro cytes was obtained Differentiation from other liver glycogen storage diseases is discussed Until now no reports on increased liver glycogen have been published

CASE REPORT

C C an 8 year-old mentally retarded girl was admitted to our hospital in May 1974 She was suffering from severe generalized GPI deficien y type Utrecht The most obvi ous clini al symptoms were a severe haemolytic disorder mental retardation muscular fatigue and liver enlarge ment (3–4 cm below the costal margin) The case report has been recently published (14) The patient was readmit ted 6 months later for revaluation and further study of the carbohydrate metabolism

METHODS

Carbohydrate metabolism was studied in vivo by different oral and parenteral tolerance tests as described by Fernandes et al (? 3 4) for differentiation of liver glycogenosis Glycogen was determined in erythrocytes after isolation by heating in alkali degradation by α-glucosidase amylase (6) and analysis of glucose by the hexokinase reaction Liver biopsy specimens were pro cessed for ultrastructural studies by current procedures Methods used for enzyme activity determinations and for study of the GPI kinetics and enzyme properties have been described elsewhere (5 14 15)

RESULTS

Morphological studies

A liver biopsy was performed after a fasting episode of 15 hours normally sufficient for exhaustion of hepatic glycogen stores In the proband however abundant cytoplasmic glycogen stored as beta particles was still pres

METHODS

Carbohydrate metabolism was studied in vivo by different oral and parenteral tolerance tests as described by Fernandes et al (2 3 4) for differentiation of liver glycogenosis Glycogen was determined in erythrocytes after isolation by heating in alkali degradation by α glucosidase amylase (6) and analysis of glucose by the hexokinase reaction Liver biopsy specimens were processed for ultrastructural studies by current procedures Methods used for enzyme activity determinations and for study of the GPI kinetics and enzyme properties have been described elsewhere (5 14 15)

RESULTS

Morphological studies

A liver biopsy was performed after a fasting episode of 15 hours normally sufficient for exhaustion of hepatic glycogen stores In the proband however abundant cytoplasmic glycogen stored as beta particles was still pres

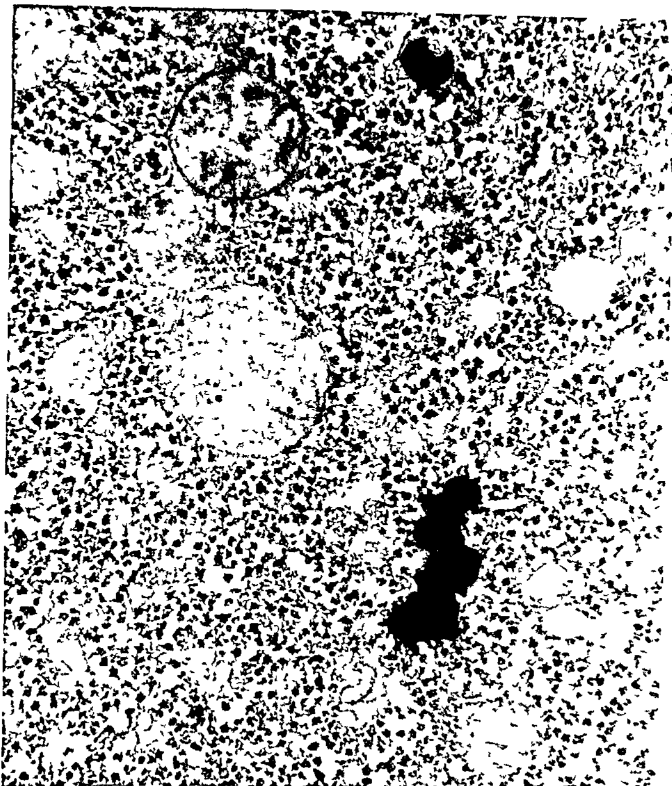

Fig 1 Electronmicroscopy of hepatic tissue The biopsy was obtained after a fasting of 15 hours Excessive amounts of glycogen stored as β particles is obvious Besides sporadic increase of mitochondrial diameter no other abnormalities could be observed No excessive fat deposition was seen (×20 000)

ent (Fig 1) The mean mitochondrial volume was normal Some mitochondria however were enlarged No excessive fat deposition was observed

Erythrocyte glycogen content

A significant increase in erythrocyte glycogen content was seen 190 µg/g Hb controls 23–64 µg/g Hb The mean corpuscular haemoglobin

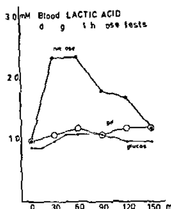

Fig 2 Comparison of the lactate response to different oral hexose tolerance tests Note the important difference of the lactate response between galactose metabolised to G 1 P glucose metabolised to G-6-P both located before the deficient GPI step and the fructose metabolised to products behind this step These tests suggest the diversion of glucose and galactose towards the glycogen pools

concentration was normal 2 050 fmole (controls 1 720–2 170)

Dietary results

A low carbohydrate diet frequent meals and avoidance of peak carbohydrate challenges resulted in a marked decrease in liver volume After 6 months of this regimen the liver volume was entirely normalized These measures however did not influence the course of the haematological condition

Studies of the carbohydrate metabolism

After an oral glucose test normal responses for glucose insulin and free fatty acids (FFA) but low levels of lactic acid (LA) were observed (Fig 2) Intramuscular *glucagon* administration was followed by a quite normal glycogenolytic response

The galactose tolerance test showed low LA response normal galactose clearing no glucose response and a very small FFA response indicating rapid disappearance of galactose towards the glycogen pools and absence of the usual stimulation of glycolysis normally resulting in a small but significant increase of LA levels (Fig 2)

The fructose tolerance test revealed a marked increase of LA and no glucose response indicating diversion of fructose towards the glycolytic sequence below the deficient GPI step (Fig 2)

These results exclude the presence of liver glycogenosis caused by deficiencies of glucose-6-phosphatase or branching and debranching enzymes and of the enzymes of the phosphorylase system (2 3 4) The normal LA increase after standardized muscular exercise compared to controls of the same age excludes muscle phosphorylase deficiency

Considering however the untrained muscular condition of our proband LA formation should have been much higher in the absence of a glycolytic disorder (8) Extensive studies on erythrocytes and leucocytes showed low GPI activity but normal or increased values of all other glycolytic enzymes (e g phosphofructokinase (PFK) this excluding PFK deficiency as a cause of glycogen storage (13)

DISCUSSION

The glycogen storage in this patient is caused by unbalance between carbohydrate intake and the metabolic capacity of the *glycolytic* sequences Normally the reversible reactions of glycolysis rarely become rate limiting for either glycolysis or gluconeogenesis (11) Considering the high molecular activity and the amounts of GPI normally large enough to maintain the reaction G-6-P↔F 6-P near its *equilibrium* one could wonder why 26% residual activity results in important cellular *dysfunction* In our patient however this equilibrium is not achieved This was demonstrated in erythrocytes by the increased [G-6-P]/[F 6 P] quotient (5 1 controls 3 1±0 5) (17) in the presence of 24% residual activity During a glycolytic flux G-6 P accumulates in hepatic GPI deficiency and four groups of enzymes compete for this substrate Embden Meyerhof hexose monophosphate (HMP) shunt glycogenic and gluconeogenic enzymes A plausible explanation of the in

the mass action ratio s of GPI in the PFK deficient muscles of Tarui s patients one could remark that the GPI equilibrium was not reached ([G-6-P]/[F 6-P] resp 5 75 5 35 6 05) The observed accumulation of G 6 P may further be caused by inhibition of GPI by erythrose-4 phosphate (1) Our observations stress the importance of studying both enzyme activities in organ systems other than blood cells and their resulting in vivo effects in GPI-deficient individuals

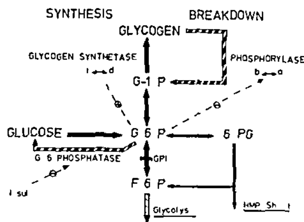

Fig 3 Mechanism of glycogen storage in glucose phosphate isomerase deficiency
G 1 P=glucose 1 phosphate G-6-P=glucose-6 phosphate F-6-P=fructose-6-phosphate 6-PG=6 phosphogluconate HMP=hexosemonophosphate shunt GPI=glucosephosphate isomerase

creased glycogen deposition could be found considering the limited metabolic capacity of the pathways normally metabolizing G 6 P The strong competitive inhibition of GPI by acyclic sugar phosphates possessing a free carbonyl group provides a negative feed back mechanism for the control of the Embden Meyerhof pathway (1) and further limits its capacity in GPI deficiency Also the diversion of G-6 P through the HMP shunt is limited by the competitive inhibition of NADPH on glucose 6 phosphate dehydrogenase (G 6 PD)

In hepatocytes the synthesis of G 6 PD could be stimulated by insulin (18 21) In contrast with our patients with glucose 6 phosphatase deficiency the plasma insulin levels during an oral glucose tolerance test were not decreased Thus increased activity of the HMP shunt could result from increased synthesis of G 6-PD However this also increases the amounts of 6 phosphogluconate erythrose-4 phosphate and sedoheptulose 7 phosphate intermediates of the HMP shunt and strong inhibitors of the GPI reaction (1) G 6-P can be dephosphorylated by glucose 6 phosphatase but the normal insulin activity results in normal depression of gluconeogenesis and promotion of glycogen synthesis and glycolysis by increasing or depressing the biosynthesis of their key enzymes (18 19 20, 21) In this way more substrate is presented to the glycogenic pathways Increased levels of G 6 P promote the interconversion of glycogen synthase to its active form and partially inhibit some steps in the phosphorylase system, this further promotes glycogen deposition (6 12) (Fig 3) The stored glycogen however can be mobilized as demonstrated during a glucagon test The disturbed equilibrium between carbohydrate intake and its disposal can be restored by restriction of carbohydrate and avoidance of peak challenges Such treatment resulted in normalization of liver volume after 6 months Besides the disorders of the enzymes of glycogen metabolism (phosphorylase phosphorylase kinase branching—& debranching enzyme and α glucosidase) glycogen storage can also occur as a secondary phenomenon in glucose 6 phosphatase and muscle PFK deficiency GPI deficiency can be classified in this cathegory

The absence of tissue specific GPI isoenzymes facilitates differentiation from other glycogen storage diseases A non spherocytic haemolytic disorder was observed in all GPI deficiencies so far described Most liver glycogen storage diseases result in liver enlargement Only moderate enlargement was present in our proband

In our patient muscular fatigue a complaint in muscle phosphorylase and muscle PFK deficiency was also present Apart from our patient liver GPI activity has never been measured in GPI deficiency Matsumoto et al (9) however noted the presence of abundant glycogen granules in the hepatic parenchymal cells of a boy with GPI Narita Mrozek et al (10) described a glycogen myopathy in a 47 year old patient suffering from muscular fatigue Defective activity of GPI was observed but PFK activity was not measured The absence of haemolytic disease could suggest an M type PFK deficiency and inhibition of GPI by a mechanism similar to that observed in Tarui s pa

the mass action ratio s of GPI in the PFK deficient muscles of Tarui s patients one could remark that the GPI equilibrium was not reached ([G 6-P]/[F 6-P] resp 5 75 5 35 6 05) The observed accumulation of G-6-P may further be caused by inhibition of GPI by erythrose-4 phosphate (1) Our observations stress the importance of studying both enzyme activities in organ systems other than blood cells and their resulting in vivo effects in GPI-deficient individuals

SISOMICIN TREATMENT OF SERIOUS NEONATAL INFECTIONS

A Clinical and Pharmacokinetic Study

P HENRIKSSON N SVENNINGSEN G KAHLMETER and K HAEGER

From the Departments of Paediatrics Malmo General Hospital Malmo and the University Hospital Lund and the Institute of Microbiology University of Lund Lund Sweden

ABSTRACT Henriksson P Svenningsen N W and Haeger K (Departments of Paediatrics University Hospital Lund and Allmanna Sjukhuset Malmo Sweden) Sisomicin treatment of serious neonatal infections A clinical and pharmacokinetic study Acta Paediatr Scand 66 317 1977 —23 infants 20 of which had verified or clinically highly suspected serious infections in the neonatal period were treated with a new antibiotic aminoglycoside sisomicin i m in doses from 2 8 to 6 6 mg/kg/24 h Clinical cure was obtained in 18 of 20 cases and marked impro ement in one case Adverse effects were only observed in two infants with tenderness at the injection sites Serum concentrations and half-life estimations showed that the concentrations were similar to those obtained for gentamicin and that half-life was independent of postnatal age but highly correlated to the gestational age and to body weight Consideration should therefore be given to the prolonged half-life of the drug in immature and low birth weight infants

KEY WORDS Aminoglycosides antibiotic treatment infections neonatal period pharmacokinetics sisomicin

Sisomicin is an antibiotic produced at the growth of *Micromonospora inyoensis* It is an aminoglycoside nearest related to the C_{1a} fraction of gentamicin the properties of which it shares to a certain extent However *in vitro* experiments and animal experimentation pointed towards a greater activity of sisomicin (4 16) Laboratory findings (16) hinted that sisomicin in therapeutic doses might have a lower ototoxic and nephrotoxic effect than that of other aminoglycosides

Only 2 clinical studies on sisomicin in the paediatric age group have been reported (3 14) The purpose of the present study was to evaluate the efficacy and tolerance of sisomicin treatment of infants with serious neonatal infections as well as to estimate the serum half life (*T/2*) in relation to gestational and postnatal age

MATERIAL AND METHODS

Twenty three newborn infants with serious systemic infections were studied The distribution of age and sex gestational week body weight diagnosis and causative organism is given in Table 1 In most cases the infection occurred concomitantly with another disease i e perinatal asphyxia (5 infants) idiopathic respiratory distress syndrome (IRDS) (10 infants) and one each with cardiac decompensation hemolytic disease (Rh immunization) recto-vaginal fistula hypoglycemia hyperbilirubinemia hypogammaglobulinemia muscular hypotonia congenital stridor facial paralysis and pharyngeal incoordination with swallowing disturbance Respiration had to be assisted in eight infants Cardiotonic drugs were given in two cases and diuretics in one case Seven infants had umbilical vein catheter during at least part of the treatment period In one case the infant received exchange blood transfusions

Administration of antibiotic

At the beginning of this investigation little was known of the adequate dosage of sisomicin in neonates Individual dosage is presented in Table 1 In three cases

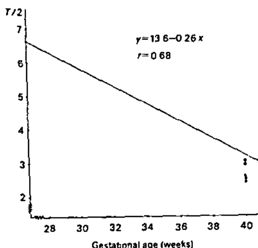

Fig 1 Serum half life (hours) in the first neonatal week in relation to maturity (gestational age) at birth

for gentamicin and tobramycin (7) Statistical calculations were made according to generally accepted principles (10)

RESULTS

Bacteriological results

The causative organism was identified in 15 cases (Table 1) and was found to be sensitive to sisomicin *in vitro* All these 15 patients reacted well on treatment with sisomicin only or a combination of sisomicin and ampicillin In 7 cases with positive culture sisomicin was the only anti infectious agent In one case of combined therapy the microorganisms were sensitive to sisomicin but not to ampicillin

Nine patients were treated with various antibiotics prior to sisomicin The results of these treatments are given in Table 2 Sisomicin treatment resulted in clinical cure in all these cases

Clinical results

In cases 2 4 7 9 and 14 the causative organism could not be isolated but hematological data (thrombocytopenia leucocytosis increased IgM or CRP) and pulmonary X ray verified the clinical signs of infection

In cases 6 8 11 infection was suspected at admission and antibiotic treatment was given but the diagnosis could not be verified neither on bacteriological nor hematological data The result of the treatment with sisomicin was thus classified as complete clinical cure in 18 of 20 cases (90%) In one case the treatment resulted in marked improvement This infant also suffered from bronchopulmonary dysplasia and hypogammaglobulinemia

In another case (no 18) all signs of clinical and bacteriological infection disappeared during treatment with sisomicin but the infant was re infected 11 days later Sisomicin was given again with bacteriologically and clinically excellent result

Adverse effects

In two patients there were signs of moderate tenderness at the injection site At follow up examinations at 6 to 14 months of age including neurological and developmental examination we did not observe any signs of auditory or vestibular damage In all patients hemoglobin white blood cells differential count platelets serum creatinine blood urea N protein and glucose in urine and microscopical urinalysis were routinely observed during and after treatment These laboratory data showed neither signs of nephrotoxicity nor hematological disturbances referable to sisomicin Fur

the daily dose was lower than 3 mg/kg In 13 treatment periods the daily dose was 3.0–3.9 mg/kg in 8 periods 4.0–4.9 mg/kg and in 5 periods greater than 5.0 mg/kg The total dose per child varied between 41 and 225 mg (mean 103±48.8 mg) All doses were administered as i m injection every 12 hours

In 15 cases ampicillin was given simultaneously with sisomicin The dose was usually 150 to 200 mg/kg/24 h in two or three injections Individual patients receiving ampicillin are listed in Table 1

Sisomicin concentrations in serum were determined with a modified agar well diffusion technique earlier used

thermore, in 7 infants glomerular filtration rate measured by single injection polyfructosan clearance test (17) within 4 weeks after sisomicin therapy was normal in all cases i e 30 5 to 59 0 ml/min/1 73 m² body surface

PHARMACOKINETICS

It is well known that serum half life of hitherto known aminoglycosides differs between children and adults (12, 15) Serum half life of sisomicin ($T/2$) was estimated by plotting the concentration of sisomicin in serum against time on semilogarithmic graph paper $T/2$ was calculated from

$$T/2=\frac{0\ 693}{\lambda}$$

in which λ is derived from

$$\log P_{siso}=\log P_{siso}0-\frac{\lambda}{2\ 303}\times t$$

For further details on half life calculation in aminoglycosides see Gyselynck et al (5)

Data for calculation of more than one half life estimation were obtained from 13 patients In these the average $T/2$ was calculated

There was no relation between the age in days and the $T/2$ according to the equation $y=4\ 3-1\ 5x$, $r=0\ 1$ However when $T/2$ was related to the gestational week at birth there was a significant correlation $T/2$ decreased by increasing maturity according to the equation $y=13\ 6-0\ 3x$, $r=0\ 68$ (Fig 1) There was also a correlation between body weight and $T/2$ Half life decreased by increasing body weight according to the equation $y=7\ 1-1\ 1x$ $r=0\ 8$ (Fig 2)

The average serum concentrations of sisomicin after a single dose are given in Table 3 Since clinical cure was complete in 90% of the cases it was not possible to correlate the clinical outcome to individual serum concentrations

DISCUSSION

It has been shown in this study that sisomicin in doses of 2 8–6 6 mg/kg/24 h is highly efficient in severe Gram negative infections in the neonatal period If the serum concentration curve was carefully monitored there was no difficulty in calculating the adequate dose No apparent adverse reactions were registered during the neonatal period or at follow up examinations In comparison Klastersky et al (8) found only one case of temporarily decreased hearing with bilateral audiometric changes among 25 urological patients on sisomicin

In investigations on newborn infants one cannot avoid combination treatment in cases of highly suspected septicemia of unknown etiology In 15 cases sisomicin was combined with ampicillin in conventional doses In these cases nothing can be concluded about the efficacy of sisomicin per se However sisomicin was the only antibiotic in 9 cases with positive culture and the treatment resulted in complete cure

Our results agree well with observations by other authors Calderón Jaimes (3) using a sisomicin dosage of 3 mg/kg/24 h reported total remission of the infection in 20 out of 22 children below 6 years of age In his series only 7 patients were younger than five months of age Orzalesi (14) used sisomicin in doses up

to 7 5 mg/kg/24 h prophylactically in preterm infants Therefore the effect cannot be evaluated

The serum concentrations of sisomicin in our series were similar to those observed after gentamic n in the same age group (9 12) This refers both to peak values and the slope of the concentration curve

Serum half life for sisomicin in adults has been calculated to between two and four hours (11 19) From Figs 1 and 2 it is evident that half life estimates in our series often were higher It appeared that the higher values were not correlated to postnatal age whereas there was a high correlation to maturity and body weight respectively From Fig 1 it is clear that *T*/2 reached adult values at a gestional age of 40 weeks This observation corresponds well with investigations on gentamicin by McCracken et al (12) and Andersen et al (1) The validity of our estimates is substantiated by a calculation from Orzalesi s (14) data for *T*/2 and body weight The regression line derived from his series ($y=7\ 4-x$) is practically identical with $y=7\ 1-1\ 1x$ as calculated from our material From the clinical view point this implies that in administration of sisomicin to preterm and low birth weight infants the prolonged half life should be taken into consideration and the dose interval accordingly adjusted

The relation of *T*/2 to the age of gestation is striking It is probably an effect of renal immaturity at birth (17) Mosegaard et al (13) in a group of 7 adult patients with decreased renal function (creatinine clearance 18±1 7 ml/min) did show conspicious increase of serum half life of sisomicin

In vitro investigations in several laboratories (6 18 20) have shown that sisomicin is more efficient than other antibiotics against e g *Klebsiella Enterobacter E coli Proteus* and *Streptococcus pyogenes* The previously reported clinical series (2 8 13 19) have shown a satisfactory clinical efficacy with a low rate of adverse reactions This series of infections in the neonatal period agrees well with these results Thus sisomicin must be considered a valuable therapeutic alternative in the treatment of serious neonatal infections

Table 3 *Average serum concentration of sisomicin in neonates*

Single dose	P_0 Mean	P_0 S D	P_{1h} Mean	P_{1h} S D	P_{2h} Mean	P_{2h} S D	P_{6h} Mean	P_{6h} S D
≤1 75 mg/kg	1 21	0 94	4 42	1 49	3 23	1 48	1 57	0 76
≥1 75 mg/kg	1 44	0 35	4 03	1 66	3 03	1 37	1 92	0 97

thermore, in 7 infants glomerular filtration rate measured by single injection polyfructosan clearance test (17) within 4 weeks after sisomicin therapy was normal in all cases i e 30 5 to 59 0 ml/min/1 73 m² body surface

PHARMACOKINETICS

It is well known that serum half life of hitherto known aminoglycosides differs between children and adults (12 15) Serum half life of sisomicin (*T*/2) was estimated by plotting the concentration of sisomicin in serum against time on semilogarithmic graph paper *T*/2 was calculated from

$$T/2=\frac{0\ 693}{k}$$

in which k is derived from

$$\log P_{siso}=\log P_{siso}0-\frac{k}{2\ 303}\times t$$

For further details on half life calculation in aminoglycosides see Gyselynck et al (5)

Data for calculation of more than one half life estimation were obtained from 13 patients In these the average *T*/2 was calculated

There was no relation between the age in days and the *T*/2 according to the equation $y=4\ 3-1\ 5x$ $r=0\ 1$ However when *T*/2 was related to the gestational week at birth there was a significant correlation *T*/2 decreased by increasing maturity according to the equation $y=13\ 6-0\ 3x$ $r=0\ 68$ (Fig 1) There was also a correlation between body weight and *T*/2 Half life decreased by increasing body weight according to the equation $y=7\ 1-1\ 1x$ $r=0\ 8$ (Fig 2)

The average serum concentrations of sisomicin after a single dose are given in Table 3 Since clinical cure was complete in 90% of the cases it was not possible to correlate the clinical outcome to individual serum concentrations

DISCUSSION

It has been shown in this study that sisomicin in doses of 2 8–6 6 mg/kg/24 h is highly efficient in severe Gram negative infections in the neonatal period If the serum concentration curve was carefully monitored there was no difficulty in calculating the adequate dose No apparent adverse reactions were registered during the neonatal period or at follow up examinations In comparison Klastersky et al (8) found only one case of temporarily decreased hearing with bilateral audiometric changes among 25 urological patients on sisomicin

In investigations on newborn infants one cannot avoid combination treatment in cases of highly suspected septicemia of unknown etiology In 15 cases sisomicin was combined with ampicillin in conventional doses In these cases nothing can be concluded about the efficacy of sisomicin *per se* However sisomicin was the only antibiotic in 9 cases with positive culture and the treatment resulted in complete cure

Our results agree well with observations by other authors Calderón Jaimes (3) using a sisomicin dosage of 3 mg/kg/24 h reported total remission of the infection in 20 out of 22 children below 6 years of age In his series only 7 patients were younger than five months of age Orzalesi (14) used sisomicin in doses up

to 7 5 mg/kg/24 h prophylactically in preterm infants Therefore the effect cannot be evaluated

The serum concentrations of sisomicin in our series were similar to those observed after gentamicin in the same age group (9 12) This refers both to peak values and the slope of the concentration curve

Serum half life for sisomicin in adults has been calculated to between two and four hours (11 19) From Figs 1 and 2 it is evident that half life estimates in our series often were higher It appeared that the higher values were not correlated to postnatal age whereas there was a high correlation to maturity and body weight respectively From Fig 1 it is clear that $T/2$ reached adult values at a gestional age of 40 weeks This observation corresponds well with investigations on gentamicin by McCracken et al (12) and Andersen et al (1) The validity of our estimates is substantiated by a calculation from Orzalesi s (14) data for $T/2$ and body weight The regression line derived from his series ($y=7\ 4-x$) is practically identical with $y=7\ 1-1\ 1x$ as calculated from our material From the clinical view point this implies that in administration of sisomicin to preterm and low birth weight infants the prolonged half life should be taken into consideration and the dose interval accordingly adjusted

The relation of $T/2$ to the age of gestation is striking It is probably an effect of renal immaturity at birth (17) Mosegaard et al (13) in a group of 7 adult patients with decreased renal function (creatinine clearance 18±1 7 ml/min) did show conspicious increase of serum half life of sisomicin

In vitro investigations in several laboratories (6 18 20) have shown that sisomicin is more efficient than other antibiotics against e g *Klebsiella Enterobacter E coli Proteus* and *Streptococcus pyogenes* The previously reported clinical series (2 8 13 19) have shown a satisfactory clinical efficacy with a low rate of adverse reactions This series of infections in the neonatal period agrees well with these results Thus sisomicin must be considered a valuable therapeutic alternative in the treatment of serious neonatal infections

CONGENITAL RICKETS

Study of the Evolution of Secondary Hyperparathyroidism

L SANN L DAVID A FREDERICH M BOVIER LAPIERRE J BOURGEOIS
M ROMAND MONIER and M BETHENOD

From the Service de Neonatologie du Professeur Maurice Bethenod et unite INSERM U 34 Hopital Debrousse Lyon France

ABSTRACT Sann L David L Frederich A Bovier Lapierre M Bourgeois J Romand Monier M and Bethenod M (service de Neonatologie du Professeur Maurice Bethenod et Unité Inserm U 34 Hopital Debrousse Lyon France) Congenital rickets Study of the evolution of secondary hyperparathyroidism Acta Paediatr Scand 66 323 1977.—A case of congenital rickets of nutritional origin is described in a light for-date premature infant (gestational age 34 weeks birthweight 1100 g) X rays of the long bones showed spread frayed and cupped metaphyses at birth and at the age of 16 days Serum calcium was 8.2 mg/100 ml phosphorus 3 4 mg/100 ml and alkaline phosphatase (A P) 323 IU/ml (N≤200) at the age of 3 days Very high level of serum immunoreactive parathyroid hormone (iPTH) was found at the age of 16 days 295 μlEq/ml (N≤50) Evidence of maternal vitamin D deficiency was demonstrated by low plasma 25 hydroxycholecalciferol (25-OH CC) 1 0 ng/ml (N 13.2±4 2) soon after delivery it was found to be normal (10.2 ng/ml) six months later Ca infusion (15 mg/kg/3 h) resulted in a marked fall of serum iPTH (280 to 84 μlEq/ml) Administration of vitamin D_2 (2400 IU/day for 10 days) induced some healing of the metaphyses A P remained elevated (400 IU/ml) plasma 25 OH CC was normal 10 2 ng/ml and serum iPTH was 115 μlEq/ml When 25 OH CC was given orally for ten days (15 μg/day) plasma 25-OH-CC rose to 64 5 ng/ml with a minor change of serum iPTH (94 μlEq/ml) X rays of the bones showed osteoporosis These results suggest a reduced conversion of 25-OH CC into 1 25-(OH)$_2$-CC

KEY WORDS Congenital rickets parathyroid hormone 25 hydroxycholecalciferol secondary hyperparathyroidism

Infantile rickets is a well known disease which still occurs Late rickets has been described in adolescent populations (12) but few neonatal rickets have been reported in the medical literature We describe a new case in which the evolution was studied by determinations of serum immunoreactive parathyroid hormone (iPTH) concentrations

CASE REPORT

The mother was a 4-year-old Caucasian who never complained of gastrointestinal symptoms or of any pain in the bones Her first pregnancy was complicated by toxemia and premature delivery at seven months of a male infant weighing 1880 g who died from intracranial bleeding at the age of ten days During the second pregnancy mild toxemia was detected therefore the mother was put on a salt restricted diet at 25 weeks of pregnancy Her daily intake of vitamin D at that time was estimated from dietary recall to be approximately 150 I U She remained in bed at home until the 34th week when a cesarean section was performed Twenty days after delivery she was found to have normal serum calcium (Ca) 10 0 mg/100 ml phosphorus (P) 4 4 mg/100 ml and alkaline phosphotases (A P) 76 IU/ml X ray films of the skeleton did not show osteomalacia Blood carotene 235 μg/100 ml (N>100) blood folate 97 6 ng/ml (N=1 9±35) and serum folate 5 1 ng/ml (N 9 ?±4 ?) were also found to be normal She was delivered of a female infant on February 7th 1975 Apgar score 8/10 The birthweight 1100 g length 39 5 cm and head circumference 28 5 cm were all under the tenth

One load dose

parathyroid serum was used as a standard reference Normal range in children and adults never exceeded 50 microliters equivalent per milliliter (μlEq/ml) Approximately 90% of normal subjects have detectable levels of serum iPTH (3)

Plasma 25 hydroxycholecalciferol (25-OH CC) was measured by a *competitive protein* binding method modified from the assay of Preece et al (16) Normal values in infants are 13 3±4 4 ng/ml Calcium infusions were *performed for three hours* with 15 mg/kg of calcium as calcium gluconate The effect of oral administration of 25 hydroxycholecalciferol (15 μg/day for ten days) on plasma 25 OH CC and serum iPTH levels was also studied

RESULTS

Twenty days after delivery, the mother's serum Ca was 10 0 mg/100 ml P 4 4 mg/100 ml A P 76 IU/ml iPTH 35 μlEq/ml plasma 25 OH-CC level was particularly low 1 0 ng/ml Six months later she had normal plasma 25 OH CC (11 0 ng/ml)

The data from her infant are shown in Table 1 Elevated serum iPTH level was detected at the age of 16 days Plasma 25-OH CC measured after administration of small doses of vitamin D_2 was found to be at the lower range of normal values Calcium infusion resulted in minimal change in serum Ca but a marked

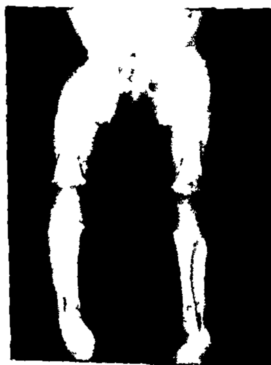

Fig 3 Roentgenogram of the legs at the age of 48 days after treatment with 15 μg 25 hydroxycholecalciferol daily for ten days No more features of rickets is observed *Shafts are* osteoporotic with marked thinning of the cortex

Fig 1 Roentgenogram of the abdomen at the age of 3 days There is a marked spread metaphysis at the distal end of the femur

percentile of Lubchenco s growth curve (11) On the second day of life she was admitted to the Hopital Debrousse for pneumoperitoneum and pneumothorax which were cured by exsufflation and oxygen therapy Initial laboratory tests showed 3610000 erythrocytes per mm³ with 15 2 g/100 ml hemoglobin 8400 white cells with 86% neutrophils Serum electrolytes were normal sodium 133 mEq/l potassium 5 2 mEq/l bicarbonates 19 5 mEq/l chloride 102 mEq/l Blood glucose was 35 mg/100 ml serum protein 4 7 g/100 ml blood urea nitrogen 18 mg/100 ml

Subsequent examination showed mildly separated sutures with normal skull bones There was no swelling at the wrists or ankles and the end of the ribs were not enlarged Serum Ca was 8 2 mg/100 ml magnesium 2 3 mg/100 ml P 3 4 mg/100 ml High alkaline phosphatase was found (323 N~150 IU/ml)

Rickets was suspected on X rays on the second day (Fig 1) and confirmed at sixteen days with spread and frayed metaphyses on the roentgenogram of the legs (Fig 2) Further studies showed urinary Ca excretion between 0 3 and 1 43 mg/kg/day and urinary P excretion between 22 and 31 2 mg/kg/day Urinary amino acids chromatography showed no abnormality The infant received 250 to 500 IU per day of vitamin D_2 I V from the second to the ninth day of life Then she was given 2400 IU/day of vitamin D_2 After administration of 600000 IU of vitamin D_2 she was discharged from the hospital at the age of eighty days At the age of three months the infant weighed 3420 g (−2 S D) length 50 cm (−2 S D) and normal head circumference (38 cm) Clinical examination and roentgenogram of the bones were satisfactory At the age of 13 months her weight was 8270 g (−1 S D) the length 75 cm (+ 1 S D) and the head circumference 46 cm (+1 S D) Clinical examination was normal and revealed four normal teeth Roentgenogram of the long bones was also normal The evolution of the biochemical data is shown in Table I

SPECIAL STUDIES

Methods

The infant was initially infused with 10% dextrose 60 to 120 ml/kg/24 h Then she was fed a commercial humanized milk providing 67 calories/100 ml with calcium 57 0 mg/100 ml and phosphorus 44 0 mg/100 ml Feeding was started at the age of nine days with 110 ml/kg/day then 175 ml/kg/day were given at the age of 21 days 200 ml/kg/day at the age of 54 days and 250 ml/kg/day the age of 60 days

Serum Ca was determined by atomic absorption and serum P according to Fiske & Subbarow (6)

Serum immunoreactive parathyroid hormone (iPTH) was measured by radioimmunoassay using an antibovine parathyroid hormone guinea pig antiserum (GP 6) a gift of Dr Constantine Anast from the Department of Pediatrics University of Missouri Hyper

Fig 2 Roentgenogram of the legs at the age of 16 days The metaphyses of the femurs are spread frayed and irregularly mineralized

1 hydroxylation may be one of the factors re sponsible for Ca malabsorption in premature infants and the need for large calcium sup plementation

It is speculated that the small amount of 1 25-(OH)$_2$ CC produced by the premature in fant could probably have healed the rickets but was insufficient to stimulate the intestinal factors (Ca binding protein (8) and/or Ca ATPase (17)) involved in Ca absorption as it was unable to correct the secondary hyper parathyroidism

ACKNOWLEDGEMENT

We have the great pleasure to thank Dr Donald Barltrop for reviewing the manus ript

decrease (69 2%) in serum iPTH was observed

When 2400 units of vitamin D_2 were given for 10 days, a normal level of plasma 25 OH CC was found a decrease in serum iPTH was observed but a normal level was not obtained Roentgenogram of the legs showed no more features of rickets When 15 µg/day of 25 OH CC was given orally for 10 days plasma level of 25 OH CC increased six fold while the decrease in serum iPTH was only 16 5% Roentgenogram of the legs showed osteoporosis at the end of 25 OH CC administration (Fig 3)

DISCUSSION

All the biochemical and radiological features found in this infant agree with the diagnosis of congenital rickets

Congenital rickets has been a well known disease since the 1914–18 war Begum et al (2) demonstrated its occurrence in newborn infants whose mothers were suffering from coeliac disease However although intestinal biopsy was not performed in the mother of this child this diagnosis was made unlikely by the absence of any clinical symptoms and by the normal concentrations of blood carotene and folate after delivery The vitamin D intake of the mother was low during the second trimester of her pregnancy furthermore she was not exposed to sunlight Therefore it is likely that the neonatal rickets was nutritional in origin This is further supported by the finding of very low level of plasma 25 OH CC in the mother soon after birth and by its spontaneous normalization 6 months later

Congenital rickets of nutritional origin has recently been described by Ford et al in Asian immigrants in Great Britain (7) Moncrieff & Fadahunsi (13) reported a similar case with low levels of plasma 25 OH CC in the mother and the newborn infant This is however the first report demonstrating the secondary hyperparathyroidism in congenital rickets by iPTH determinations According to Lamb & Stanbury (10) a marked decrease in serum iPTH under Ca infusion indicates that hyperparathyroidism is not autonomous In the patient persistant hyperparathyroidism was found despite normal levels of serum Ca and plasma 25 OH CC Moreover, when 25 OH CC was given orally plasma 25 OH CC increased six fold hence excluding intestinal malabsorption Serum iPTH fall was however small (less than 20%) and it remained far above the normal range

A direct suppressive effect of vitamin D on iPTH by the parathyroid cells has been demonstrated (10 15) and evidence for such an effect in a case of congenital hyperparathyroidism secondary to maternal hypoparathyroidism has been reported (18) Recently Chertow et al (4) attributed this effect to 1 25 dihydro xycholecalciferol (1 25 (OH) CC) since administration of physiological doses of 1 25 $(OH)_2$ CC to rachitic rats resulted in a 40% decrease in serum PTH The minor change in serum PTH which occurred in spite of marked increase in plasma 25 OH CC level observed in this infant suggests a limitation in conversion of 25 OH CC into 1 25 OH CC

Osteoporosis is a common finding in tiny premature infants It is usually attributed to the low Ca intake in comparison to the amount a fetus receives from its mother (5 19) The diet given to our infant did not provide daily amounts of calcium comparable to the theoretical values and this could explain the occurrence of osteoporosis Intestinal Ca absorption is also poor in premature infants (1 8 21) it does not depend solely on fat malabsorption and it increases with fetal and post natal age Furthermore it is not adapted to the requirements and the body stores of calcium as in children and adults (5) 1 25 $(OH)_2$ CC plays a major role in intestinal Ca absorption (15) and it has been shown that its serum level increases with calcium restricted diets (9) In this case osteoporosis was observed despite 25 OH CC administration and elevated plasma 25 OH CC levels It is suggested that reduced

1 hydroxylation may be one of the factors responsible for Ca malabsorption in premature infants and the need for large calcium supplementation

It is speculated that the small amount of 1 25-$(OH)_2$-CC produced by the premature infant could probably have healed the rickets but was insufficient to stimulate the intestinal factors (Ca binding protein (8) and/or Ca ATPase (17)) involved in Ca absorption as it was unable to correct the secondary hyperparathyroidism

SEVERE DISSEMINATED ADENOVIRUS INFECTION SUCCESSFULLY TREATED WITH A THYMIC HUMORAL FACTOR THF

I VARSANO T M SCHONFELD Y MATOTH B SHOHAT T ENGLANDER V ROTTER and N TRAININ

From the Department of Pediatrics and the Clinical Laboratory Beilinson Medical Center Tel Aviv University Medical School Petah Tikva and the Department of Cell Biology the Weizmann Institute of Science Rehovot Israel

ABSTRACT Varsano I Schonfeld M Matoth Y Shohat B Englander T Rotter V and Trainin N (Department of Pediatrics and the Clinical Laboratory Beilinson Medical Center Tel Aviv University Medical School Petah Tikva and Department of Cell Biology the Weizmann Institute of Science Rehovot Israel) Severe disseminated adenovirus infection successfully treated with a thymic humoral factor THF Acta Paediatr Scand 66 329 1977.—Adenovirus and other usually benign viral infections may occasionally be associated with severe fulminant disease often accompanied by acute acquired cellular immunodeficiency Thymic humoral factor derived from calf thymuses has been demonstrated to have the capacity to restore the immunocompetence of immature incompetent T cells This factor was used in the treatment of a 3½ year-old boy who was critically ill with an adenovirus infection and presented evidence of immunocellular deficiency Within less than 48 hours after the institution of treatment with thymic humoral factor there was a dramatic progressive clinical improvement with restoration of the cellular immunocompetence It is suggested that thymic humoral factor may be beneficial in the treatment of severe viral infections associated with depressed cellular immunocompetence

KEY WORDS adenovirus infection viral infection thymic humoral factor cellular immunodeficiency

Infection with adenovirus which is usually associated with mild febrile conditions (14) occasionally develops into a severe disseminated illness (1 9 15) It has been suggested that in such patients the fulminant course of the disease may be due to a deficiency in the defense mechanism of the host (2 3)

Thymic humoral factor (THF) is a polypeptide with hormone like activity which has been isolated recently from calf thymuses (4 16) In vitro and in vivo studies performed both in animals and in humans have shown that THF and other thymic factors have the capacity to enhance and restore the cellular immune response by inducing maturation of T lymphocytes (6 11 16 18 19) Up till the present time the clinical use of these thymic factors has been very limited (18 19)

The present report concerns a child with severe disseminated adenovirus infection and transient depression of the cell mediated immunocompetence (CMI) who made a remarkable recovery with reconstitution of the CMI following the administration of THF

CASE REPORT

A 3½ year-old boy was hospitalised because of acute respiratory infection of 4 days duration The child had been hospitalised repeatedly for the same reason since the age of one month No congenital abnormality of the respiratory tract was found and the levels of serum immuno-

globulins and of sweat electrolytes were normal On admission his temperature was 40 5 C There was severe respiratory distress with clinical and radiological evidence of diffuse bilateral interstitial pneumonia The liver and spleen were palpable 4 and 3 cm respectively below the costal margin The white blood cell count was 7 1 10^9/l with a shift to the left and lymphopenia of 13% (0 923 10^9/l) LDH was 10 58 μmol s^{-1}/l SGOT 1 151 μmol s^{-1}/l prothrombin 0 35/l total proteins 63 g/l albumin 35 g/l IgG 8 0 arb unit IgA 1 8 arb unit IgM 0 78 arb unit Secretory IgA was present in the saliva Routine urine examinations were normal

Evaluation of the cellular immunocompetence showed total T-cells (as tested by the E rosette test) 0 22 10^9/l (normal values in our laboratory for children in this age group are 1 4±0 3 10^9/l±S D) migratory inhibition factor (MIF) index of 0 95 and 0 9 with PPD and Concanavalin A respectively (standard MIF ≤0 8) (10) and negative skin tests to antigens of Candida at a dilution of 1 1000 Trychophyton 1 1000 PPD 2 tuberculin units and streptokinase streptodornase 1 1

Despite 4 days of intensive supportive therapy including cephalexin and prednisone (2 mg/kg/d) the child s clinical condition deteriorated further Melena appeared and he became comatose with depressed spontaneous respiration The child was intubated and mechanical ventilation instituted The cerebrospinal fluid was normal Electroencephalogram tracing revealed a diffuse slowing of the cortical activity There was no evidence of disseminated intravascular coagulation Serum glucose and ammonia were normal During the following 3 days the child s condition continued to deteriorate Chest X rays demonstrated extension of the pulmonic infiltrates and the child remained in deep coma

A fulminant viral disease was suspected and from the seventh day of hospitalisation THF was administered at a dose of 2 mg/kg/d intramuscularly with the aim of restoring the impaired CMI At the same time prednisone was tapered off Within 24 hours a dramatic clinical improvement was observed manifested by the appearance of spontaneous breathing and adequate oxygenation of the blood after discontinuation of the mechanical ventilation One day later the child s temperature fell to normal and he regained consciousness Seven days following institution of THF treatment there was a significant reduction in respiratory distress and partial resolution of the interstitial findings in the lungs The electroencephalographic pattern had also returned to normal THF was discontinued after 2 weeks of administration and 7 days later the child was discharged with minimal residual lung findings

Re-evaluation of the CMI following THF administration revealed an increase in the absolute number of T cells to 1 38 10^9/l and 1 78 10^9/l on the third and fifth days of treatment respectively This increase was maintained in 5 additional examinations made during the following 11 months The MIF index against PPD and Concanavalin A was normal (0 80 and 0 78 respectively) on the tenth day of treatment as well as on two later occasions Skin tests repeated after 5 weeks showed a positive reaction to streptokinase streptodornase (12 mm induration and 18 mm erythema) as they did after 5 months

Infection with type 3 adenovirus was diagnosed based on the isolation of the virus from tracheal aspirate and a rise in titer of complement fixing antibodies from 1 16 on the fifth day of hospitalisation to 1 256 on the 17th day

DISCUSSION

In the patient described severe interstitial pneumonia encephalopathy and hepatic damage resulting from the adenovirus infection were associated with impaired CMI which most probably was acquired during the illness The reconstitution of CMI following the administration of THF was associated with a strikingly rapid clinical improvement unusual in the course of such a fulminant disease (1 15)

In patients with disseminated adenovirus infections the humoral immunity is usually normal (12 13) although severe lymphopenia (<1 5 10^9/l) is common (1–3) Transient lymphopenia and a decrease in the number of T cells have also been reported in other viral infections (2 7 11 17) The finding of normal lymphatic tissue in such patients suggests an acute acquired form of cellular immunodeficiency (1) Severe adenovirus infection has been reported in patients with thymic alymphoplasia (20) as well as in other conditions associated with an impaired CMI e g in malnourished children (5) and following measles (12)

The importance of intact cellular immunoresponsiveness for recovery from viral infections is well known (8) The striking clinical improvement concomitant with restoration of the CMI which was observed in our patient can almost certainly be related to the THF administered particularly since this and other thymic factors have already been shown to have the capacity to restore CMI in various pathological conditions (4 18 19) including viral infections in humans (11)

Although no definite conclusions can be drawn on the basis of a single case it is suggested that therapy with THF may be beneficial in the treatment of life threatening viral infections associated with a depressed CMI

ABSTRACT Lind T Gerrard J Sheridan T S and Walker W (MRC Reproduction and Growth Unit Princess Mary Maternity Hospital Newcastle upon Tyne and Department of Haematology Royal Victoria Infirmary Newcastle upon Tyne Northumberland UK) Effect of maternal parity and infant sex upon the haematological values of cord blood Acta Paed atr Scand 66 333 1977.—Coulter Counter (Model S) analysis of 400 cord blood samples are presented together with differential white cell counts for 249 of these The mean values for haemoglobin and red cell count are somewhat higher than previous values determined by manual methods while those for haematocrit and mean cell volume are slightly lower An unexpected finding was that the red cell count haemoglobin concentration and haematocrit are significantly higher in male than in female infants A parity effect was also demonstrated Infants of both sexes born as second or subsequent births had lower values for total white cell count haemoglobin concentration and haematocrit than first born infants

KEY WORDS Haemoglobin white blood count red blood count cord blood parity infant sex

Most reports on detailed analyses of human cord blood are over 20 years old (2 3 4 5 6 8 9) The values were no doubt determined with care and precision but by manual techniques which are much less accurate and less reproducible than automated methods (7)

A paper by Xanthou (10) reported the use of a Coulter counter to determine the total white cell count (WBC) in a group of healthy new born babies but did not report on other haematological indices We have not found any reports of full cord blood analysis in any large group of infants using modern analytical techniques It is the purpose of this paper to report data obtained by Coulter counter analysis of 400 umbilical venous blood samples together with the differential white cell counts in 249 of these

MATERIALS AND METHODS

Infants

Samples were obtained from over 400 virtually consecutive deliveries no attempts were made to select the type of patient or infant other than to exclude those infants known to be affected by rhesus haemolytic disease Because of the fragility of white cells under storage conditions it was often the case that samples collected from infants delivered between 12 00 noon on Saturdays and midnight on Sundays were unsuitable for white cell counting by the Monday morning Such samples were discarded as were any showing evidence of clot formation the survey was terminated on completion of 400 acceptable samples

Coulter analysis

Blood was obtained from an umbilical vein in the placental end of the cord immediately upon clamping This blood was put into a standard sequestrene tube and sent for analysis or kept at 4 C from overnight deliveries until collected for analysis Determinations were performed routinely on the Coulter equipment (Model S) used for the regular hospital service

EFFECT OF MATERNAL PARITY AND INFANT SEX UPON THE HAEMATOLOGICAL VALUES OF CORD BLOOD

T LIND J GERRARD T S SHERIDAN[1] and W WALKER[2]

From the MRC Reproduction and Growth Unit Princess Mary Maternity Hospital Newcastle upon Tyne [1] and the Department of Haematology Royal Victoria Infirmary Newcastle upon Tyne [2] Northumberland UK

Males	4 64±0 53 (22)	4 70±0 4 (137)
Females	4.59±0 37 (18)	4 56±0.37 (139)
Both sexes	4 67±0 44 (40)	4 63±0 40 (276)
Hb (g/dl)		
Males	16 74± 22 (22)	16 99±1 70 (137)
Females	16 89±1 51 (18)	16 41±1.37 (139)
Both sexes	16 81±1 91 (40)	16 0±1.57 (276)
HCT (l/l)		
Males	0 489±0 060 (22)	0 496±0 049(137)
Females	0 495±0 046 (18)	0 479±0 047(139)
Both sexes	0 49 ±0 053 (40)	0 488±0 046(276)
MCV (fl)	106 07±4 38 (40)	105 07±4 40 (276)
MCH (pg)	36 6±1 50 (40)	36 00±1 40 (276)
MCHC (g/dl)	34 08±1 00 (40)	34 19±1 03 (276)

22 4% at 41 weeks 5 2% at 42 weeks and 2 2% at 43 or more completed weeks

Method of delivery A normal vaginal delivery occurred in 79 8% by forceps in 14 2% an assisted breech delivery in 3 1% and by Caesarean section in 2 8% Some under representation of deliveries by Caesarean section was caused by lack of sufficient staff in theatre to take the collection of blood samples from all cases otherwise the figures are reasonably representative of the usual hospital annual experience

Numbers of samples Full blood counts were available on 400 samples and the percentage of reticulocytes was estimated for 316 of these differential white cell counts were available on 249 samples but 20 of these patients had uncertain menstrual dates

Sex related differences When the means and standard deviations for the various estimates were calculated it was found that male infants had a significantly higher red blood count (RBC) haemoglobin concentration (Hb) and haematocrit (Hct) than female infants but there was no significant difference for any of the other determinations (Table 1)

Centile values To make the data as representative of normal infants as possible the calculations were based upon the 276 infants delivered between 37 and 41 completed weeks of gestation who weighed over 2 5 kg and who did not require any special care at or after delivery The values are given in Table 2 and are for both sexes with the exception of RBC Hb and Hct where the sex specific values were calculated

Differential WBC There was a great variation in the percentage of neutrophils found in the 249 samples examined and it was ascertained that the neutrophil value was not correlated with the total WBC irrespective of the value of the latter ($r=0\ 049$) The percentage of neutrophils is very similar for all values of total WBC whether this be less than ten thousand per mm³ or over eighteen thousand On many occasions the neutrophil count was less than 45% again this was not related to the total WBC and occurred with equal incidence over the whole range of white cell counts It was quite sufficient to examine the percentage of neutrophils because the percentage of lymphocytes complemented it to 100% for all practical purposes

The data were examined in some detail to determine whether the haematological values were related in any way to fetal maternal or delivery characteristics

Admission to the intensive care nursery The most obvious group in whom changes might have been anticipated were those babies requiring special care immediately after delivery There were 40 such infants and their data were compared with the 276 infants described above No significant differences were found (Table 3) Their values were then distributed in relation to the centiles from the normal babies and again no significant differences were found

Birth weight Over the whole group no correlation could be demonstrated between birth

Table 1 *Means and standard deviations of the various estimates by infant sex (Occasions where males differ from females are indicated in the last column)*

Differential counts

It was not possible to undertake a differential count in every case and out of 400 cases in which white cell counts were obtained differential counts were made in only 249 After staining with Leishmann stain two independent technicians each counted two groups of 100 cells and the mean of these four counts was reported twenty five slides were recounted by the same technicians under blind conditions and 20 slides randomly chosen from the remainder were counted by an independent observer While there were differences in the differential counts none of these was significant and the data reported here are the original findings

RESULTS

Infant sex and birthweight There were 203 male infants with a mean birth weight of 3 40±0 50 kg and 197 females with a mean birth weight of 3 25±0 46 kg Calculating from the first day of the last menstrual period in the 362 patients who had reliable dates 1 1% were delivered at 33 completed weeks or less 3 9% at 34 or 35 weeks 3 6% at 36 weeks 3 6% at 37 weeks 58 0% at 38–40 weeks,

Table 2 *Centile values of the various estimates for babies delivered between 37 and 41 completed weeks of gestation weighing over 2 5 kg and not admitted to the special care nursery (276 infants both sexes unless otherwise indicated)*

globin and red cell count are somewhat higher than previously found while those for haematocrit and mean cell volume are slightly lower (2 3 4 5 6 8 9) The haematocrit change is explicable on the grounds that trapped plasma is not included with a Coulter analysis but the association with a lower MCV was unexpected

We have not found any report that describes an effect of fetal sex upon the red cell count haemoglobin concentration or haematocrit It has been argued that the lower haemoglobin concentration found in women during their childbearing years is due to the iron loss caused by menstruation or to the iron demands of pregnancy This hypothesis is apparently supported by the fact that the haemoglobin concentration rises after the menopause However an alternative suggestion could be that the hormonal status of women particularly their sex steroid status over their fertile years leads to altered haemopoiesis and that the lower haemoglobin concentration is the physiological norm for that period of their life (1) Certainly during pregnancy a time of considerable oestrogen and progesterone increase the maternal haemoglobin concentration decreases It can thus be postulated that the female fetus may respond to the hormonal environment of pregnancy in the same way that she will respond to her own hormonal change after puberty

It is less easy to think of a plausible explanation for the parity effect It cannot be explained by infants of greater birth weight labours of shorter duration the method of delivery or the length of time the membranes have been ruptured Whatever the origin of this effect it applies to male and female fetuses alike

weight and any of the haematological variables.

Length of gestation. No correlations could be found between the cord blood values and length of gestation but there were few babies below 36 completed weeks.

Onset of labour. The data derived from babies born after a spontaneous onset of labour differed in no respect from those born following induction of labour. The mothers were then divided into three groups according to the time elapsing from the membranes rupturing to the infant being born (under 6 hours, 6–9 hours and over 9 hours); no significant differences were found for any of the haematological variables.

Method of delivery. The haematological findings were the same for babies born as spontaneous cephalic deliveries, with the use of forceps, by breech presentation or by Caesarean section with one exception. The mean white cell count was significantly higher (at the 5% level) in babies delivered by the use of forceps compared with the other three groups. However, 90% of the patients so delivered were primigravidae and raised the possibility that the difference was due to parity rather than the method of delivery. To test this the white cell count of forceps delivered infants of primigravid patients was compared with the counts of normally delivered infants of primigravid patients; no significant differences were found.

Parity. To determine whether parity had any effect only those women having normal vaginal deliveries and whose babies did not need to go to the special care nursery were considered. This of course reduced the number available for study (294) but made a comparison between the parity groups cleaner. The data are given in Table 4 and demonstrate that the values for white cell count, red cell count, haemoglobin and haematocrit are significantly greater for first born infants than for second or subsequent births; the sex differences are also maintained within each group. The other haematological variables did not show a parity difference.

CONCLUSIONS

Comparisons of our findings with previously reported values are affected by differences of methodology. Our mean values for haemo

globin and red cell count are somewhat higher than previously found while those for haematocrit and mean cell volume are slightly lower (2 3 4 5 6 8 9) The haematocrit change is explicable on the grounds that trapped plasma is not included with a Coulter analysis but the association with a lower MCV was unexpected

We have not found any report that describes an effect of fetal sex upon the red cell count haemoglobin concentration or haematocrit It has been argued that the lower haemoglobin concentration found in women during their childbearing years is due to the iron loss caused by menstruation or to the iron demands of pregnancy This hypothesis is apparently supported by the fact that the haemoglobin concentration rises after the menopause However an alternative suggestion could be that the hormonal status of women particularly their sex steroid status over their fertile years leads to altered haemopoiesis and that the lower haemoglobin concentration is the physiological norm for that period of their life (1) Certainly during pregnancy a time of considerable oestrogen and progesterone increase the maternal haemoglobin concentration decreases It can thus be postulated that the female fetus may respond to the hormonal environment of pregnancy in the same way that she will respond to her own hormonal change after puberty

It is less easy to think of a plausible explanation for the parity effect It cannot be explained by infants of greater birth weight labours of shorter duration the method of delivery or the length of time the membranes have been ruptured Whatever the origin of this effect it applies to male and female fetuses alike

ON INDICATIONS FOR TREATMENT OF THE HYPERPHENYLALANINEMIC NEONATE

FLEMMING GUTTLER and ERIK WAMBERG

From the John F Kennedy Institute Glostrup Denmark

ABSTRACT Guttler F and Wamberg E (The John F Kennedy Institute DK 2600 Glostrup Denmark) On indications for treatment of the hyperphenylalaninemic neonate Acta Paediatr Scand 66 339 1977.—Of 488 006 neonates tested by Guthrie screening 58 showed values above 2.5 mg/100 ml Thirty two showed values between 2 5 mg/100 ml and 15 mg/100 ml Eighteen of these infants appeared to have phenylketonuria (PKU) and fourteen to have persistent hyperphenylalaninemia (HPA) Neither the initial Guthrie test value nor the confirmatory test were able to differentiate between these two conditions. Consequently a phenylalanine restricted diet is started in any child with serumphenylalanine values exceeding 10 mg/100 ml (605 μmol/l) The data show that the course of the dietary tolerance of phenylalanine and a 24-hour phenylalanine load test will differentiate infants with PKU from those with HPA

KEY WORDS Neonatal hyperphenylalaninemia phenylketonuria phenylalanine tolerance indications for treatment

Blood amino acid screening of newborn babies has revealed heterogeneity in disorders related to the hydroxylation of phenylalanine to tyrosine (8 17 18) Early blood screening has enabled us to correct these metabolic disorders within the first few weeks of life (5 13 20) However the improvement in early detection and treatment of newborn children with elevated blood phenylalanine has hampered our possibilities of distinguishing those who require a phenylalanine restrictive dietary therapy e g children with phenylketonuria (PKU) from those who do not e g children with persistent hyperphenylalaninemia (HPA) according to previous diagnostic criteria such as the appearance of a positive ferric chloride reaction (7)

The present data show that initial screening values as well as serum phenylalanine and tyrosine concentrations in confirmatory fluorimetric tests may be misleading Thus seven babies who later appeared to have phenylketonuria showed confirmatory serum phenylalanine values in between 10 and 15 mg/100 ml (605–910 μmol/l) between the 9th and 22nd days of life Consequently a phenylalanine restricted diet is started in any child with serum phenylalanine values exceeding 10 mg/100 ml (605 μmol/l) Weekly estimates of the dietary tolerance of phenylalanine and a 24 hour phenylalanine load test at 6 months of age are used as the criteria for the differentiation of children with PKU from those with HPA

MATERIAL AND METHODS

This study includes 58 infants seen in Denmark with a positive Guthrie screening test (9) over a 9-year period (1967–1975) The Guthrie screening in Denmark is centralized in one laboratory and usually performed at the age of 5 to 7 days When a presumptive positive result was observed the phenylalanine and tyrosine concentration in serum were examined by a fluorimetric assay (see below) in additional samples of blood taken 4 to 15 days later Guthrie testing covered 0 1% newborn babies in Den

	♀	4	6	16
Total		21	11	26

mark in 1967 increasing to 77 7% of all newborns in 1971 and 99 5% of the newborns in 1975

Phenylalanine was determined by an adaptation (10) of the fluorimetric method of McCaman & Robins (16) using 25 µl of serum The accuracy of the method was tested by comparing the values obtained by fluorimetry to column chromatography of 20 samples ranging from 95–665 µmol/l The correlation coefficient was 0 93

Tyrosine was determined by a microadaptation of the fluorimetric method of Udenfriend (19) using 150 µl of serum (10) Twenty two samples measured by this method and by column chromatography showed a correlation coefficient of 0 88 Serum standards with known amounts of phenylalanine and tyrosine were used in the fluorimetric assays in place of aqueous solutions of amino acids

The phenylalanine tolerance of a child was calculated weekly as the amount of phenylalanine in mmoles per kg body weight tolerated per day in order to keep the serum phenylalanine level within 180–425 µmol/l (3–7 mg/100 ml) The protein intake was kept at 13% of the intake of calories and the part of protein tolerated as natural protein was determined by the actual serum phenylalanine value of the child

For oral phenylalanine loading L phenylalanine (BDH Chemicals Ltd Poole England) was completely dissolved in 0 01 N HCl and the pure solution was given orally after an overnight fast in a dose of 0 6 mmol per kg body weight Phenylalanine loading performed according to this practice revealed maximum serum phenylalanine concentrations within the first hour after phenylalanine administration (11) The loading tests were performed in order to classify children with elevated blood phenylalanine The children were usually loaded at an age of six months

The criteria for HPA were 1) serum phenylalanine below 605 µmol/l (10 mg/100 ml) on a normal dietary intake of phenylalanine (approx 0 7 mmol per kg body weight) 2) a slight rise in serum tyrosine within the first four hours after phenylalanine loading 3) serum phenylalanine returning to preloading levels within 24 hours after a load of 0 6 mmol L phenylalanine per kg body weight (10) The criteria for PKU were 1) serum phenylalanine within 180–425 µmol/l (3–7 mg/100 ml) on a phenylalanine restricted diet (0 09–0 27 mmol per kg body weight per day) 2) no rise in serum tyrosine following phenylalanine loading 3) preloading levels of serum phenylalanine attained 48 hours or more after a load of 0 6 mmol L phenylalanine per kg body weight The criteria for classical versus mild PKU are discussed in a previous paper (11) Briefly to keep serum phenylalanine levels within 180–425 µmol/l (3–7 mg/100 ml) children with classical phenylketonuria tolerate 9–18% and children with the mild form of phenylketonuria 22–36% of a normal daily intake of phenylalanine This distinction cannot be made until the child is more than 2½ years of age (11)

The intellectual development (Cattell) was determined by the same psychologist who was not aware of the diagnoses of the children

RESULTS

Initial blood values

Of 58 newborn infants detected by the Guthrie technique 21 showed an initial blood phenylalanine value of 10 mg/100 ml or lower eleven showed values in between 10 mg/100 ml and 15 mg/100 ml and 26 showed blood phenylalanine values above 15 mg/100 ml (Table 1) Eight of the children in the first group appeared to have PKU and 13 to have HPA In the second group 10 appeared to have PKU and one HPA All the children in the third group appeared to have PKU (Table 1) At the time of screening 23 of the 44 children with PKU were breast fed It should be noticed that only half of the PKU children with Guthrie values below 10 mg/100 ml were breast fed (Fig 1)

Confirmatory serum values

Phenylalanine and tyrosine were determined fluorimetrically in confirmatory tests taken between the 9th and 22nd days of life. The values of phenylalanine and tyrosine as well as the ratio of tyrosine² over phenylalanine and of phenylalanine² over tyrosine differed significantly in infants with PKU as compared to infants with HPA. However, the overlapping ranged from 21–54%. The median serum tyrosine value of infants with PKU was 84 µmol/l (range 41–124 µmol/l) and of infants with HPA 103 µmol/l (range 72–186 µmol/l) $p<0.02$. Thus, no infants with HPA showed

confirmatory serum tyrosine values below 72 μmol/l (1 3 mg/100 ml)

Nine infants who appeared to have PKU showed confirmatory serum phenylalanine values below 910 μmol/l (15 mg/100 ml) (Table 2) Five of these children have reached an age of 2½ years and it appears that four have the *mild form of PKU and only one the classical* form of PKU Of the 32 children with confirmatory phenylalanine values above 910 μmol/l 22 have reached the age of 2½ years Eighteen of these children have the classical form of PKU and four the mild form of PKU χ^2 7 47 $p<0.01$

Phenylalanine tolerance and load test

Within the first month of life six of 14 children with HPA showed values of serum phenylalanine above 605 μmol/l (10 mg/100 ml) These children were treated according to our practice with a phenylalanine restricted diet However to keep their blood phenylalanine concentration within therapeutic levels the dietary intake of phenylalanine was increased to normal levels within a few months (Fig 2) As shown in Table 2 the phenylalanine tolerance of children with HPA was normal at one year of age

All of the 14 children with HPA showed the same course of *phenylalanine loading* i e no significant increase in serum tyrosine but fasting levels of serum phenylalanine attained within 24 hours after loading (Fig 3) The 24 hour value is significantly different from that observed in children with PKU and no overlapping has hitherto been observed (Fig 3)

DISCUSSION

Regardless of how many forms of disturbances in the metabolism of phenylalanine we may be able to distinguish the possibility to differentiate newborn children who require a dietary therapy from those who do not is essential Recently Bickel (2) and Blaskovics et al (3) *have stressed that the use of an arbitrary* and fixed blood phenylalanine level (e g 20 *mg/100 ml) as the diagnostic criterion for* treatment may be hazardous The present finding that 9 babies who later appeared to have PKU showed confirmatory serum values of phenylalanine (fluorimetric assay) below 910 μmol/l (15 mg/100 ml) between the 9th and 22nd days of life indicates that in these cases *the early clinical diagnosis of PKU can be* made only by weekly estimations of the dietary tolerance of phenylalanine (Fig 2) unless the enzyme activity is determined in liver biopsies

It may be that some of our children classified as PKU would have developed normally on an unrestricted diet *However the* therapeutic level of serum phenylalanine used *in the present study* is generally accepted as beneficial to intellectual development in the treatment of PKU if it is introduced within the first weeks of life (5 13 20) Examination of 72 untreated mentally retarded patients with *PKU revealed 5 patients with phenylalanine* levels (fluorimetric assay) below 910 μmol/l

(15 mg/100 ml) in three separate specimens on a normal protein intake Furthermore six untreated mentally retarded patients with PKU with serum phenylalanine levels below 1031 µmol/l (17 mg/100 ml) and no explanation of their mental deficiency other than PKU showed phenylalanine loading tests consistent with PKU but not with HPA (data to be published)

The finding that 18 of 32 newborns with Guthrie values below 15 mg/100 ml later appeared to have PKU could not be due to the age at testing as all babies were tested between the 5th and 7th days of life nor to the diet of the baby e g breast feeding versus an infant formula (Fig 1) (4 6) However the type of phenylalanine hydroxylase deficiency e g mild versus classical PKU may explain the low Guthrie screening value

The children with HPA reported in this study may be similar to the cases studied by Levy et al (14) None of their subjects had received any form of dietary treatment However the I Q s of the affected subjects were normal and comparable to those of the unaffected siblings School grades of the affected children attending school were good In the present study 6 of 14 children with HPA were given phenylalanine free hydrolysates during their first month of life in low amounts as compared to our schedule for the treatment of PKU The median Cattell scores of the untreated group were 108 (range 107–110) and those of the treated group 108 (range 98–113)

The guide lines for the interpretation of elevated phenylalanine in neonates drawn up in the present study may seem quite simple as compared with the more detailed classification proposed by Berry et al (1) Menkes & Holtzman (15) and Blaskovics et al (3) However it has recently been reported that children with PKU treated within the first 10 days of life obtained higher I Q scores than children started on treatment later (5) The present investigation shows that within the first 10 days of life PKU children may have phenylalanine concentrations between 10 and 15 mg/100 ml We suggest that if the phenylalanine concentration in a confirmatory test is between 605 and 910 µmol/l (10–15 mg/100 ml) treatment with phenylalanine restricted diet should be undertaken The serum phenylalanine concentration should be tested with intervals of 2 days and the phenylalanine intake maintained at a sufficiently high level to keep serum phenylalanine levels in the range of 180–425 µmol/l (3–7 mg/100 ml) A firm diagnosis can be established within the following weeks using estimations of the phenylalanine tolerance of the baby Finally it should be noticed that this article does not deal with transient elevations of both phenylalanine and tyrosine or permanent elevation of phenylalanine due to tyrosinosis Out of 488 006 neonates screened in Denmark we have not detected any case of phenylalanine transaminase deficiency nor of dihydropteridine reductase deficiency (12)

ACKNOWLEDGEMENT

Intelligence testing was performed by psychologist Hanne Bjørner We thank the staff of the John F Kennedy Institute for their valuable help and advice Financial support was received from the Danish Health Insurance Foundation (grant no 116/87 5313) the Research Committee of the Danish Mental Retardation Service (project no 93) and P Carl Petersens Found

DISCUSSION

Regardless of how many forms of disturbances in the metabolism of phenylalanine we may be able to distinguish *the possibility to dif* ferentiate newborn children who require a dietary therapy from those who do not is es sential Recently Bickel (2) and Blaskovics et al (3) have stressed that the use of an arbitrary *and fixed blood phenylalanine level* (e g 20 mg/100 ml) as the diagnostic criterion for treatment may be hazardous The present find ing that 9 babies who later appeared to have PKU showed confirmatory serum values of phenylalanine (fluorimetric assay) below 910 μmol/l (15 mg/100 ml) between the 9th and 22nd days of life indicates that in these cases *the early clinical diagnosis of PKU* can be made only by weekly estimations of the diet ary tolerance of phenylalanine (Fig 2) unless the enzyme activity is determined in liver biopsies

It may be that some of our children classified as PKU would have developed nor mally on an unrestricted diet However the therapeutic level of serum phenylalanine used in the present study is generally accepted as beneficial to intellectual development in the treatment of PKU if it is introduced within the first weeks of life (5 13 20) *Examination of* 72 untreated mentally retarded patients with PKU revealed 5 patients with phenylalanine *levels (fluorimetric assay)* below 910 μmol/l

(15 mg/100 ml) in three separate specimens on a normal protein intake Furthermore six untreated mentally retarded patients with PKU with serum phenylalanine levels below 1 031 µmol/l (17 mg/100 ml) and no explanation of their mental deficiency other than PKU showed phenylalanine loading tests consistent with PKU but not with HPA (data to be published)

The finding that 18 of 32 newborns with Guthrie values below 15 mg/100 ml later appeared to have PKU could not be due to the age at testing as all babies were tested between the 5th and 7th days of life nor to the diet of the baby e g breast feeding versus an infant formula (Fig 1) (4 6) However the type of phenylalanine hydroxylase deficiency e g mild versus classical PKU may explain the low Guthrie screening value

The children with HPA reported in this study may be similar to the cases studied by Levy et al (14) None of their subjects had received any form of dietary treatment However the I Q s of the affected subjects were normal and comparable to those of the unaffected siblings School grades of the affected children attending school were good In the present study 6 of 14 children with HPA were given phenylalanine free hydrolysates during their first month of life in low amounts as compared to our schedule for the treatment of PKU The median Cattell scores of the untreated group were 108 (range 107–110) and those of the treated group 108 (range 98–113)

The guide lines for the interpretation of elevated phenylalanine in neonates drawn up in the present study may seem quite simple as compared with the more detailed classification proposed by Berry et al (1) Menkes & Holtzman (15) and Blaskovics et al (3) However it has recently been reported that children with PKU treated within the first 10 days of life obtained higher I Q scores than children started on treatment later (5) The present investigation shows that within the first 10 days of life PKU children may have phenylalanine concentrations between 10 and 15 mg/100 ml We suggest that if the phenylalanine concentration in a confirmatory test is between 605 and 910 µmol/l (10–15 mg/100 ml) treatment with phenylalanine restricted diet should be undertaken The serum phenylalanine concentration should be tested with intervals of 2 days and the phenylalanine intake maintained at a sufficiently high level to keep serum phenylalanine levels in the range of 180–425 µmol/l (3–7 mg/100 ml) A firm diagnosis can be established within the following weeks using estimations of the phenylalanine tolerance of the baby Finally it should be noticed that this article does not deal with transient elevations of both phenylalanine and tyrosine or permanent elevation of phenylalanine due to tyrosinosis Out of 488 006 neonates screened in Denmark we have not detected any case of phenylalanine transaminase deficiency nor of dihydropteridine reductase deficiency (12)

ACKNOWLEDGEMENT

Intelligence testing was performed by psychologist Hanne Bjørner We thank the staff of the John F Kennedy Institute for their valuable help and advice Financial support was received from the Danish Health Insurance Foundation (grant no H6/87 5313) the Research Committee of the Danish Mental Retardation Service (project no 93) and P Carl Petersens Found

EFFECT OF OBESITY ON THE HYPOTHALAMO PITUITARY-GONADAL FUNCTION IN CHILDHOOD

E CACCIARI A CICOGNANI P PIRAZZOLI F ZAPPULLA P TASSONI F BERNARDI S SALARDI and L MAZZANTI

From the Department of Paediatrics University of Bologna Bologna Italy

ABSTRACT Cacciari E Cicognani A Pirazzoli P Zappulla F Tassoni P Bernardi F Salardi S and Mazzanti L (Department of Paediatrics University of Bologna Bologna Italy) Effect of obesity on the hypothalamo-pituitary-gonadal function in childhood Acta Paediatr Scand 66 345 1977.—In 22 normal and 35 obese boys a gonadal function test (2 000 IU of hCG i m daily for three days and assays of plasma testosterone before and after the hCG administration) was carried out All the short normal children and 31 obese subjects underwent the LH RH test (50 μg i v) While basal testosterone was similar in the two groups of children after hCG testosterone was significantly ($p<0.001$) lower in the obese boys In the normal children a significant positive correlation between bone age and basal and after hCG testosterone was demonstrated this correlation was not found in the obese boys The pituitary reserve of gonadotrophins did not show significant differences between the two groups of children Finally a significant positive correlation ($p<0.01$) between the LH curve area during the LH RH test and bone age was found only in the normal boys.

KEY WORDS Obesity testosterone LH FSH

Gabrilove et al (8) found that Cushing s syndrome in the male is often associated with a decreased endocrine testicular efficiency which then becomes normal after the treatment of the disease Hajjar et al (11) showed that an ACTH excess through the adrenal mediation minimizes in the male the testosterone release of the gonads Since Dunkelman et al (7) Garces et al (9) and Migeon et al (12) state that the function of the pituitary adrenal axis is increased in obesity since Borjeson (2) says that the fertility of the obese adult is impaired and since Amatruda et al (1) report less testosterone release in the obese adult we have studied the endocrine function of the gonads and the pituitary reserve of gonadotrophins in the prepubertal obese child

MATERIALS AND METHODS

22 "short normal" boys (chronological age ranged from 5 to 11 7/12 years mean 8 7/12 bone age ranged from 4 8/12 to 11 7/12 years mean 8 6/12) and 35 obese boys (chronological age ranged from 4 6/12 to 12 3/12 years mean 8 9/12 bone age ranged from 4 6/12 to 12 years mean 9 1/12) were studied Bone age was determined according to the Greulich & Pyle tables (10) In the control group the difference between the chronological and the bone age was never greater than six months In the obese children the difference was never greater than 1 1/12 year In the second group obesity had been existing for at least three years and the mean weight was 57% over the ideal weight (from 41% to 98%) according to the Tonelli & Marinelli tables (16) No child had lost any weight in the year preceding this study All the children examined were in the prepubertal stage of sexual development i e the first stage according to Tanner (15) The X rays of the sella turcica of the same children were normal

All of the children following permission from the parents underwent a gonadal function test all the normal children and 31 obese subjects underwent the LH RH (Luteinizing Hormone Releasing Hormone) test The

or the FSH pituitary reserve As far as the LH is concerned we found a highly significant positive correlation ($r=+0.610$ $p<0.01$) between the area of the curve and bone age only in the normal children No correlation was found between LH and testosterone both in basal conditions and after stimulus

DISCUSSION

Our results show that in the obese child the testosterone release by the gonads after hCG is significantly lower than in normal children The different behaviour of the gonadal endocrine function in the obese child is confirmed by the lack of correlation (which was found on the contrary in the normal child) between basal or after hCG testosterone and bone age Since the pituitary reserve of LH and FSH is similar in the two groups of subjects the different behaviour of the gonadal endocrine function found in the obese child might be originally attributed to the gonads We must point out that since both groups received the same dose of hCG the obese children were given a smaller amount per kg of gonadotrophins and this may be the reason for the lower testosterone response But we must also mention that since the target tissue (the gonads) was the same in the two groups the weight of the child is probably not very important

Another point to be taken into consideration is the different absorption rate of the drug in the two groups but we feel that the duration of the test limits the possibility of such an event We might ask whether the endocrine defect that we found could refer to a simple delay in the gonadal maturation and therefore would disappear during puberty The lower release of testosterone found in the obese adult by Amatruda et al (1) would tend to support a permanent relationship between obesity and the gonadal endocrine function no matter what the age of the patient may be However this fact is not simple to valuate Tanaka et al (14) when examining male patients after surgery noticed a significant decrease in the urinary excretion of 17 ketosteroids together with a significant increase in the urinary excretion of 17 hydroxy-corticosteroids Gabrilove et al (8) and Hajjar et al (11) showed that the adrenal hypersecretion typical of some pathological situations is accompanied by a decrease in the release of testosterone by the male gonads All these data seem to demonstrate a decrease in the testosterone release when there is an adrenal hypersecretion Being aware of the adrenal hypersecretion in obesity (7 9 12) our data seem to confirm the existence of a relationship between the adrenal and the gonadal function in the obese child

$p<0\ 001$

LH RH test was performed (before the gonadal function test) at 9 a am after an overnight fast using venous injec tion of 50 μg of synthetic LH RH (Farbwerke Hoechst AG) Venous blood for the evaluation of LH and FSH was collected at times 0 15 30 60 and 90 min The gonadal function test was carried out in the following manner hCG (Human Chorionic Gonadotrophin) was administered at a dosage of 2 000 IU i m every day for three days The dose was administered at 9 a m on the first two days and at 6 a m on the third day Immediately before the beginning and at the end of the test a blood sample was collected to assay plasma testosterone (4)

Plasma testosterone was determined according to the radioimmunoassay method of Collins et al (6) The antiserum we used was obtained from rabbits pretreated with an antitubercular vaccine as we have previously re ported (5) The antiserum was used at a dilution of 1 30000 The method sensitivity was 0 5 ng/100 ml the intra assay coefficient of variation was ±4 2% Serum LH and FSH were evaluated according to the double antibody radioimmunoassay method of Reuter et al (13) using hu man pituitary LH and FSH (the radioimmunological equivalent of LH is 2 150 IU as compared to the 68/40 reference preparation of the National Institute for Medical Research (MRC) Mill Hill London for FSH it is 2 800 IU compared to 68/39 reference preparation of MRC) The results are expressed as mIU/ml MRC reference prepara tion The method sensitivity was 0 5 mIU/ml both for LH and FSH The intra assay coefficient of variation was ±7 4% and ±8 5% for LH and FSH respectively

For the statistical analysis of the results the Student s t test was used and the correlation coefficient r was calcu lated

RESULTS

The mean basal plasma testosterone value (Table 1) did not present any significant differ ences between the two groups of children Af ter the hCG stimulus the plasma testosterone level in the obese children was significantly lower ($p<0\ 001$) than that of the normal children (Table 1) In the normal children there is a significant positive correlation between bone age and basal ($r=+0\ 718$ $p<0\ 001$) or after hCG testosterone ($r=+0\ 472$ $p<0\ 05$) This correlation is not found in the obese children

The mean FSH curve during the LH RH test does not show any significant differences between the two groups (Table 2) The mean LH curve is constantly lower in the obese children and the difference is significant only at the 15th minute ($p<0\ 05$) The pituitary re serve of gonadotrophins was also studied by evaluating the peak the maximum increase and the area of the curve (3) (Table 2) and it did not show any significant differences be tween the two groups of children In both the normal children and the obese there is no cor relation between bone age and the basal values

DISCUSSION

Our results show that in the obese child the testosterone release by the gonads after hCG is significantly lower than in normal children The different behaviour of the gonadal endocrine function in the obese child is confirmed by the lack of correlation (which was found on the contrary in the normal child) between basal or after hCG testosterone and bone age Since the pituitary reserve of LH and FSH is similar in the two groups of subjects the different behaviour of the gonadal endocrine function found in the obese child might be originally attributed to the gonads We must point out that since both groups received the same dose of hCG the obese children were given a smaller amount per kg of gonadotrophins and this may be the reason for the lower testosterone response But we must also mention that since the target tissue (the gonads) was the same in the two groups the weight of the child is probably not very important

Another point to be taken into consideration is the different absorption rate of the drug in the two groups but we feel that the duration of the test limits the possibility of such an event We might ask whether the endocrine defect that we found could refer to a simple delay in the gonadal maturation and therefore would disappear during puberty The lower release of testosterone found in the obese adult by Amatruda et al (1) would tend to support a permanent relationship between obesity and the gonadal endocrine function no matter what the age of the patient may be However this fact is not simple to valuate Tanaka et al (14) when examining male patients after surgery noticed a significant decrease in the urinary excretion of 17 ketosteroids together with a significant increase in the urinary excretion of 17 hydroxy-corticosteroids Gabrilove et al (8) and Hajjar et al (11) showed that the adrenal hypersecretion typical of some pathological situations is accompanied by a decrease in the release of testosterone by the male gonads All these data seem to demonstrate a decrease in the testosterone release when there is an adrenal hypersecretion Being aware of the adrenal hypersecretion in obesity (7 9 12) our data seem to confirm the existence of a relationship between the adrenal and the gonadal function in the obese child

ACKNOWLEDGEMENTS

We thank in particular Dr F Enzmann and Dr M Sesso (Farbwerke Hoechst AG) for the generous supply of synthetic LH RH and Alfa Formaceutici for cooperation in the antisera production The skilful technical assistance of Mr L Zannarini is gratefully acknowledged

ASYMPTOMATIC BACTERIURIA IN SCHOOLGIRLS

VI The Correlation between Urinary and Faecal Escherichia coli Relation to the Duration of the Bacteriuria and the Sampling Technique

G LIDIN JANSON and U LINDBERG

From the Departments of Clinical Bacteriology and Immunology Institute of Medical Microbiology and Departments of Infectious Diseases and Pediatrics University of Goteborg Goteborg Sweden

ABSTRACT Lidin Janson G and Lindberg U (Departments of Clinical Bacteriology and Immunology Institute of Medical Microbiology and Departments of Infectious Diseases and Pediatrics University of Goteborg Goteborg Sweden) Asymptomatic bacteriuria in school girls VI The correlation between urinary and faecal *Escherichia coli* Relation to the duration of the bacteriuria and the sampling technique Acta Paediatr Scand 66 349 1977.—The occurrence of the urinary strain in the anus rectum and faeces was investigated in 27 girls with asymptomatic bacteriuria (ABU) In patients with bacteriuria of relatively short duration 46 % of the faecal isolates were of the urinary strain as compared to only 18 % in patients with bacteriuria of relatively long duration In general the correlation between the urinary and faecal flora is striking at the time of establishment of ABU but diminishes with time The diminished correlation may be due to two factors firstly the composition of the faecal flora changes with time Secondly the correlation may be obscured by complex changes in the properties of bacterial strains established in the urinary tract Contamination by the infected urine did not seem to be a serious problem when the rectal mucosa was swabbed proximal to the anal canal

KEY WORDS Asymptomatic bacteriuria *E coli* faecal flora

Escherichia coli infecting the urinary tract usually originate in the patient s own bowel flora (17) Analyses of the correlation between the urinary and the faecal flora may be of importance for an understanding of the host parasite relationship in urinary tract infection (15) Such analyses have to take into account the two possibilities of contamination of the faecal specimen by the infected urine and of colonization of the gut by a strain already established in the urinary tract (3 7) A longitudinal study of schoolgirls with asymptomatic bacteriuria (9) offered an opportunity to study the problems of sampling the faecal flora in bacteriuria and to analyse the relationship between the urinary and faecal flora

MATERIAL AND METHODS

Patients

The patients were all included among the schoolgirls with asymptomatic bacteriuria (ABU) described and prospectively followed up treated or untreated by Lindberg (9 10) Twenty seven bacteriuric children attending the clinic for their scheduled appointments during a five month period took part in this study Patients harbouring O typable urinary strains were preferred The 27 patients were grouped according to the duration of their ABU Seventeen patients were classified as having bacteriuria of relatively long duration They were either still bacteriuric with the strain originally found on screening or had a re infection strain carried for at least one year Two of these patients had new infections during the study period Together with ten others they were then classified as having ABU of relatively short duration that is reinfections of 0–11 months duration

Sampling

Without preliminary cleansing a cottonwool swab was rotated superficially in the anus After that two swab

H+=haemolysis in solid medium

[a] Only two out of ten cultures grew enterobacteria Neither of two colonies corresponded to the urinary strain

Only six out of ten cultures grew enterobacteria Four out of six colonies corresponded to the urinary strain

[c] None out of ten cultures grew enterobacteria

After a ten-day course of nitrofurantoin one negative urine culture obtained in EL 4 months and in EA 3 weeks before indicated specimen

[f] 0+=very small amount of strain found by selection for colony morphology

covery of the urinary strains from the swabs from the anus and rectum is summarized in Table 1 In no instance was the urinary strain recovered from the rectum but not from the anus In eight instances it was found in the anus but not in the plain rectal swab and in seven cases in the anus but not in the rectal swab taken through the tube In these specimens the urinary strain thus occurred more often in the anal swab than in either of the rectal swabs (Sign test)

The overall proportion of stool isolates conforming with the urinary strain present was 399/875 isolates (45 6%) in the group with bacteriuria of short duration and 250/1404 (17 8%) in bacteriuria of long duration The proportions of isolates corresponding to the urinary strain found among 60 randomly selected colonies were compared for the twelve episodes of bacteriuria of short duration (*A*) and the seventeen episodes of long duration (*B*) Table 2 In group *A* 5 patients had 0–20 concordant colonies and 6 had 41–60 colonies In group *B* 15 girls had only 0–20 colonies conforming to the urinary strain The two distributions are different at the 5% level of significance (Fisher s permutation test)

The same bacteriuria strain was found more than once in nine girls The characteristics of the urinary strains and the numbers of colonies from each sampling site—anus rectum and faeces—that corresponded to the urinary strain of each patient are shown in Table 3

Three girls (ME EL and MH) had recent re

One rectal swab (R_2) was taken through a sterile tube inserted into the anal canal

Pattern of occurrence of the urinary strain	No of cases
$A-R_1-R_2-$	11
$A+R_1+R_2+$	3
$A+R_1-R_2-$	7
$A+R_1-R_2+$	1
$A-R_1$ and/or R_2+	0

specimens were taken from the rectum the stick inserted to a mark 40 mm from the tip In endeavour to minimize contamination from the anal canal one of the swabs was inserted through a small tube The tubes were made from heat sterilizable nylon They were 30 mm long with an internal diameter of 8 mm a rounded inner tip and a flange at the outer end Sterile vaseline was applied to the tip and the tube was passed through the anal canal the flange being firmly pressed against the skin The order of taking the two rectal swabs in each case was randomized

Each swab was put into a tube with transport medium (13) and kept at +4 C until cultured usually later the same day Material for the collection of faecal specimens at home was dispensed and careful instructions were given The girl was asked first to urinate into the lavatory basin After wiping herself carefully she was then to deliver the faeces directly into a large plastic bag placed in a suitable container The bag was to be sealed and put into an insulating box with cold accumulators The boxes were collected from the patients homes usually within twelve hours of defaecation

Bacteriological procedure

The faecal specimens which were all formed were cut into pieces using a red hot metal rod At each of three roughly equidistant points one swab was bored into the centre of one cut surface There were thus six swabs from each patient one anal two rectal and three faecal swabs

Each swab was inoculated ten times on a modified Conradi Drigalski agar The inocula were spread with a platinum loop The plates were incubated aerobically at 37 C overnight

The last colony growing from each of the ten cultures was then subcultured as were representatives of any colony types not included among these The subcultures were typed as previously described (8) The procedure included a simplified *E coli* O grouping using mono and multivalent antisera against 69 O groups in all Strains that agglutinated spontaneously were designated Sa Haemolysin production was assessed in plates with 5% washed horse erythrocytes Antibiotic sensitivity was tested using a disc diffusion method (5) Strains conforming to the urinary strain with respect to O agglutination pattern haemolytic capacity and antibiogram were preserved as deep agar stab cultures under sterile paraffin oil usually one colony from each positive site Urinary strains were preserved in the same manner The preserved strains were later subjected to a limited K antigen typing with the serum agar technique (2) Strains giving no precipitates around the colony on any of the plates were designated KNt O and K nontypable strains found in the urine and the faeces of the same patient were biotyped according to their pattern of fermentation of 16 carbohydrates as described by Bettelheim & Taylor (1)

Statistical calculations

The sign test (4) and Fisher s permutation test (14) were used

RESULTS

Thirty nine sets of specimens were obtained from the 27 patients All but two of the anal swabs and five of the swabs from two faecal specimens yielded *Enterobacteriaceae* from all ten spread out cultures Altogether 2279 colonies were randomly selected and typed

Out of these 649 isolates (28 5%) were found to concord with the urinary strain present The rates of concordance at the different sampling sites were 40 2% for the anus 31 8% for the rectum when the tube was not used and 30 3% when it was The overall figure for the faeces proper was 22 7% and the range between the faeces swabs I II and III was from 19 4 to 24 9%

In twenty two episodes of bacteriuria the urinary strain was not found on at least one occasion among thirty randomly selected isolates from the innermost part of the faeces The re

specimens were taken from the rectum the stick inserted to a mark 40 mm from the tip In endeavour to minimize contamination from the anal canal one of the swabs was inserted through a small tube The tubes were made from heat sterilizable nylon They were 30 mm long with an internal diameter of 8 mm a rounded inner tip and a flange at the outer end Sterile vaseline was applied to the tip and the tube was passed through the anal canal the flange being firmly pressed against the skin The order of taking the two rectal swabs in each case was randomized

Each swab was put into a tube with transport medium (13) and kept at +4 C until cultured usually later the same day Material for the collection of faecal specimens at home was dispensed and careful instructions were given The girl was asked first to urinate into the lavatory basin After wiping herself carefully she was then to deliver the faeces directly into a large plastic bag placed in a suitable container The bag was to be sealed and put into an insulating box with cold accumulators The boxes were collected from the patients homes usually within twelve hours of defaecation

Bacteriological procedure

The faecal specimens which were all formed were cut into pieces using a red hot metal rod At each of three roughly equidistant points one swab was bored into the centre of one cut surface There were thus six swabs from each patient one anal two rectal and three faecal swabs

Each swab was inoculated ten times on a modified Conradi Drigalski agar The inocula were spread with a platinum loop The plates were incubated aerobically at 37 C overnight

The last colony growing from each of the ten cultures was then subcultured as were representatives of any colony types not included among these The subcultures were typed as previously described (8) The procedure included a simplified *E coli* O grouping using mono and multivalent antisera against 69 O groups in all Strains that agglutinated spontaneously were designated Sa Haemolysin production was assessed in plates with 5% washed horse erythrocytes Antibiotic sensitivity was tested using a disc diffusion method (5) Strains conforming to the urinary strain with respect to O agglutination pattern haemolytic capacity and antibiogram were preserved as deep agar stab cultures under sterile paraffin oil usually one colony from each positive site Urinary strains were preserved in the same manner The preserved strains were later subjected to a limited K antigen typing with the serum agar technique (2) Strains giving no precipitate around the colony on any of the plates were designated KNt O and K nontypable strains found in the urine and the faeces of the same patient were biotyped according to their pattern of fermentation of 16 carbohydrates as described by Bettelheim & Taylor (1)

Statistical calculations

The sign test (4) and Fisher s permutation test (14) were used

RESULTS

Thirty nine sets of specimens were obtained from the 27 patients All but two of the anal swabs and five of the swabs from two faecal specimens yielded *Enterobacteriaceae* from all ten spread out cultures Altogether 2 279 colonies were randomly selected and typed

Out of these, 649 isolates (28 5%) were found to concord with the urinary strain present The rates of concordance at the different sampling sites were 40 2% for the anus 31 8% for the rectum when the tube was not used and 30 3% when it was The overall figure for the faeces proper was 22 7% and the range between the faeces swabs I II and III was from 19 4 to 24 9%

In twenty two episodes of bacteriuria the urinary strain was not found on at least one occasion among thirty randomly selected isolates from the innermost part of the faeces The re

§ 0+=very small amount of strain found by selection for colony morphology

covery of the urinary strains from the swabs from the anus and rectum is summarized in Table 1 In no instance was the urinary strain recovered from the rectum but not from the anus In eight instances it was found in the anus but not in the plain rectal swab and in seven cases in the anus but not in the rectal swab taken through the tube In these specimens the urinary strain thus occurred more often in the anal swab than in either of the rectal swabs (Sign test)

The overall proportion of stool isolates conforming with the urinary strain present was 399/875 isolates (45 6%) in the group with bacteriuria of short duration and 250/1 404 (17 8%) in bacteriuria of long duration The proportions of isolates corresponding to the urinary strain found among 60 randomly selected colonies were compared for the twelve episodes of bacteriuria of short duration (*A*) and the seventeen episodes of long duration (*B*) Table 2 In group *A* 5 patients had 0–20 concordant colonies and 6 had 41–60 colonies In group *B* 15 girls had only 0–20 colonies conforming to the urinary strain The two distributions are different at the 5% level of significance (Fisher s permutation test)

The same bacteriuria strain was found more than once in nine girls The characteristics of the urinary strains and the numbers of colonies from each sampling site—anus rectum and faeces—that corresponded to the urinary strain of each patient are shown in Table 3

Three girls (ME EL and MH) had recent re

duration was defined as a fairly recent recurrence established within 0–11 months Bacteriuria of long duration was defined as either persistence of the strain harboured when bacteriuria was first detected at screening or of a recurrence established at least one year earlier

In the first group 46% of the pooled faecal isolates corresponded to the urinary strain compared to 18% in the second group In the individual patients the proportions of the urinary strains found among 60 faecal isolates were differently distributed in the short-duration and the long-duration bacteriuria group (*Table 2*) In the former group there was a bimodal distribution and in the latter there was a shift towards a low proportion of the urinary strain in the faecal flora The development was clearly illustrated by some of the girls in whom the same bacteriuria strain was found more than once (Table 3)

These findings corroborate the interpretation given by Roberts et al (15) to their results from a study of bacteriuria in non pregnant women The correspondence between urinary and faecal *E coli* was lower in ABU than in symptomatic infection Since bacteria infecting the urinary tract commonly originate in the patient s faecal coliform flora (7 17 18) and since the faecal flora changes at intervals (16) it was concluded that when symptoms develop they probably do so in most cases within a short time of the infection becoming established In most cases of ABU on the other hand the infection will have been established long enough for the faecal flora to have changed (15) The possibility of colonization of the gut from the urinary tract (3 15 18) might explain the divergent findings in the rectal swabs and the faeces proper in a few cases e g EA and KK Table 3 It may well be that urine containing at times millions of viable *E coli* per millilitre exerts a stabilizing influence on the normal flora of either mainly the rectum *via* true retrograde colonization or also of the faeces proper *via* the retrograde or the oral route Such a mechanism might explain some recurrences with strains identical to that found at the preceding infection as in the girls EA and EL (Table 3)

Generally however the dynamics of the faecal flora will in time eliminate the strain that once became established in the urinary tract In the urinary tract on the other hand the strain may undergo complex changes of its antigenic and biochemical properties (1 11) In one girl (EJ) the present urinary *E coli* SaK1 was considered to be a degraded variant of the O18 K1 originally found in her urine and still a minority strain in her faecal flora Thus a strain may sometimes remain stable in the faecal flora while the clone established in the urinary tract changes under selective pressures exerted in this milieu

ACKNOWLEDGEMENTS

This work was supported by grants from the Medical Faculty of Göteborg the Göteborg Medical Association the First of May Flower Annual Campaign for Children s Health and the Swedish Medical Research Council (Project no 215)

The skilful technical assistance of Helena Lomberg Ingela Delgado Lilian Nilsson and Stina Wallenkrans is very much appreciated

currences of asymptomatic bacteriuria with a strain not present at the latest check up two to six months earlier In all of these there was a strong correlation between urinary and faecal *E coli* At the next control examination, two to five months later the correlation had disappeared in two of the girls, EL and MH A similar pattern was observed in KK and AKW both of whom had entered the ABU study eight months earlier when their bacteriuria was detected at screening In KK on the second occasion the strain was still found in the anal and rectal swabs, but not in the faeces proper In one girl (MJ), only selection for colony morphology showed the urinary strain to be present in the rectum and faeces

On the first sampling occasion three girls (EA TS and AS) harboured a urinary strain which had been present for at least one year In TS, the strain was not found in any of the swabs and in AS it occurred in varying proportions at all sites In EA three colonies conforming to the urinary strain were found in the rectum and two in the faeces proper on the first occasion On the second occasion more than half of the colonies from the innermost part of the faeces but none of the isolates from the anus or rectum were of the same strain In this girl as in EL one negative urine culture had been obtained after a short course of nitrofurantoin, but bacteriuria with the same strain had recurred

One girl EJ not included in Table 3 had originally harboured a urinary *E coli* O 18 K1 biotype A (1) At the time of the study the urinary strain was SaK1 not fermenting salicin but otherwise with the same fermentation pattern In one rectal and one faecal swab one isolate indistinguishable from the original bacteriuria strain was found

DISCUSSION

One of the aims of the present study was to study the methodological problems involved in sampling the faecal flora in bacteriuria In a preliminary study (unpublished) 33 girls with asymptomatic bacteriuria had their anuses swabbed before and on the morning after a bladder wash out with neomycin solution (6 12) In 20 cases a negative urinary culture was obtained at the same time as the second anal swab A strain corresponding to the urinary *E coli* was found in 12 girls both before and after the wash out in 13 patients neither before nor after, and in 8 before but not after the wash out In these cases the recovery probably represented passive contamination of the anal region and not true colonization

In endeavour to obtain a clean catch faecal specimen one approach was to analyze the interior of a specimen of faeces delivered as far as possible separately from urination This should represent the gut flora oral to the rectum

Another approach was to sample the flora of the rectal ampulla The swab then had to pass through the probably contaminated anus We tried to assess the importance of this by analyzing duplicate rectal swabs one being introduced through a small tube The tip of the tube may have carried some urinary bacteria so the shielding was not expected to be perfect The variation between the results of the two rectal swabs in each patient was however strikingly small and very similar to that between different swabs from the same specimen of faeces proper When the urinary strain corresponded to less than one in thirty colonies from the innermost part of the faeces correspondence was greater in the anal swabs than in the rectal swabs of either kind (Table 1) Thus when the rectal mucosa was swabbed proximal to the anal canal superficial contamination did not seem to be of any great importance

The apparent degree of correlation between urinary and faecal flora in patients with bacteriuria may thus be influenced by the sampling technique Apart from this an important difference was revealed when the girls of the present study were divided into two groups depending on the duration of their bacteriuria with the present strain Bacteriuria of short

weeks of gestation cord serum LDL cholesterol values are found to be much higher than in full term mature newborns

In betamethasone treated AGA infants born before the 37th week of gestation the concentration of cord serum HDL cholesterol was found to be higher than in untreated AGA infants below 37 weeks of gestation

MATERIAL

All children in the study were taken from our screening program for hyperlipoproteinemia which so far includes 7065 consecutive live born infants from Copenhagen Only newborns without signs of perinatal asphyxia (i e no meconium stained amniotic fluid fetal heart rate above 120/min during delivery no circumflexion of the umbilical cord and 1 min AS>7) were chosen to avoid cases with TNH Otherwise no selection of the newborns was made If the birthweight was above the 10th percentile value for gestation the infant was classified as AGA If the birth weight was below the 10th percentile value for gestation the infant was classified as SGA

A total of 30 full term mature newborns 35 full term SGA infants and 26 purely premature newborns were studied 10 of whom had been treated with betamethasone prior to delivery Another 5 newborns being both *SGA and prematurely born were not included in the* study since this number was too small for statistical evaluation

The betamethasone treatment was given in the following way

Table 2 *Cord serum lipid and lipoprotein cholesterol concentrations in mmol/l in 35 SGA infants born between the ≥37th≤42th week of gestation*

Pregnant mothers entering the Rigshospital in Copenhagen in labor before the 37th week of pregnancy were given 12 mg of betamethasone i m immediately and this was repeated once 24 hours later. In addition 100 mg of Ritodrine in 1000 ml of 5.5% glucose was given i v over a 24 hour period and 100 mg of peroral phenobarbital divided into 3 doses was given daily until birth had taken place.

In the present study no matching was done between pairs of treated and untreated AGA infants <37 weeks of gestation.

Sampling. The umbilical cord was clamped and cut within the first 3 min after birth and prior to delivery of the placenta. Mixed arterial and venous cord blood was allowed to run freely, contamination with maternal blood being carefully avoided. The cord blood was stored at 4°C for no longer than 12 hours before serum was separated (2 000 r p m, 20 min) and the analyses begun.

METHODS

Total cholesterol (T-C) and triglyceride (TG) were determined as previously described by Andersen & Gry Nielsen (5). (VLDL+LDL)-cholesterol was measured in the following way: 200 µl of cord serum was mixed with 2.0 ml 0.05 M $CaCl_2$ and 40 µl 1% heparin (1 560 U/ml) at 20–30°C. After exactly 4 min the mixture was centrifuged for 10 min at 6000 r p m. The clear supernatant (HDL) was decanted, the tube left upside-down for 10

min and the precipitate (VLDL+LDL) redissolved in 200 μl 1.7% NaCl solution and the concentration of cholesterol determined LDL-cholesterol was calculated from the formula LDL-cholesterol (mmol/l)=(VLDL+LDL)-cholesterol (mmol/l) − TG (mmol/l)/2.15 HDL cholesterol was calculated from the formula HDL cholesterol (mmol/l)=total cholesterol (mmol/l) − (VLDL+LDL) cholesterol (mmol/l)

Statistics Percentile values were calculated to characterize the distribution of the different lipid and lipoprotein-cholesterol values For comparison of cord serum lipid and lipoprotein-cholesterol values among newborns with different gestational age the Mann Whitney test was used as described by Siegel (6)

RESULTS

In Tables 1–3 cord serum lipid and lipoprotein cholesterol values are given for AGA and SGA infants born after the 37th week of gestation and for AGA *infants born before the 37th week* of gestation

In Table 4 cord serum lipid and lipoprotein cholesterol values are given for AGA betamethasone treated infants born before the 37th week of gestation

In Table 5 a comparison is made between these groups and it is seen that the concentration of cord serum VLDL cholesterol and triglyceride is significantly higher in SGA infants compared with AGA infants born after the 37th week of gestation

A comparison between AGA infants born before and after the 37th week of gestation shows significantly higher values of total cholesterol LDL-cholesterol and HDL cholesterol in AGA *infants <37th week*

The betamethasone treated AGA infants <37 weeks are seen to have significantly higher total cholesterol and HDL cholesterol than AGA infants <37 weeks who had not been treated

DISCUSSION

The finding in the present study of significantly higher concentration of cord serum triglyceride in SGA infants compared with AGA infants born after the 37th week of gestation is

in agreement with the findings of Tsang et al (3) Fosbrooke & Wharton (7) as well as Andersen & Friis Hansen (4)

The cause of the association between IUGR and elevated cord serum triglyceride remains speculative Christensen (8) found elevated cord serum FFA values in infants born after IUGR This might indicate an increased lipolysis in these fetuses and infants but as long as the minute volume of the placenta and the exchange of FFA across the placenta cannot be measured in humans the question remains unanswered although the first step to elucidating this important question has been taken by Hull (9) who demonstrated a rapid exchange of [1 ^{14}C]palmitate from the mother to the fetus In contrast to the present study Fosbrooke & Wharton (7) found significantly higher cord plasma triglyceride in full term than in preterm newborns

As for total cholesterol Rafstedt (10) has previously reported that cord plasma total cholesterol concentration was the same in infants with a birth weight below and above 2 500 g However he did not assess the gestational age of the infants and thus did not differentiate between AGA and SGA infants

Fosbrooke & Wharton (7) did not find any

min and the precipitate (VLDL+LDL) redissolved in 200 µl 1.7% NaCl solution and the concentration of cholesterol determined. LDL cholesterol was calculated from the formula: LDL-cholesterol (mmol/l)=(VLDL+LDL)-cholesterol (mmol/l)−TG (mmol/l)/2.15. HDL cholesterol was calculated from the formula: HDL cholesterol (mmol/l)=total cholesterol (mmol/l)−(VLDL+LDL) cholesterol (mmol/l).

Statistics. Percentile values were calculated to characterize the distribution of the different lipid and lipoprotein-cholesterol values. For comparison of cord serum lipid and lipoprotein-cholesterol values among newborns with different gestational age, the Mann Whitney test was used as described by Siegel (6).

RESULTS

In Tables 1–3 cord serum lipid and lipoprotein cholesterol values are given for AGA and SGA infants born after the 37th week of gestation and for AGA infants born before the 37th week of gestation.

In Table 4 cord serum lipid and lipoprotein cholesterol values are given for AGA betamethasone treated infants born before the 37th week of gestation.

In Table 5 a comparison is made between these groups and it is seen that the concentration of cord serum VLDL cholesterol and triglyceride is significantly higher in SGA infants compared with AGA infants born after the 37th week of gestation.

A comparison between AGA infants born before and after the 37th week of gestation shows significantly higher values of total cholesterol, LDL cholesterol and HDL cholesterol in AGA infants <37th week.

The betamethasone treated AGA infants <37 weeks are seen to have significantly higher total cholesterol and HDL cholesterol than AGA infants <37 weeks who had not been treated.

DISCUSSION

The finding in the present study of significantly higher concentration of cord serum triglyceride in SGA infants compared with AGA infants born after the 37th week of gestation is

in agreement with the findings of Tsang et al (3) Fosbrooke & Wharton (7) as well as Andersen & Friis Hansen (4)

The cause of the association between IUGR and elevated cord serum triglyceride remains speculative Christensen (8) found elevated cord serum FFA values in infants born after IUGR This might indicate an increased lipolysis in these fetuses and infants but as long as the minute volume of the placenta and the exchange of FFA across the placenta cannot be measured in humans the question remains unanswered although the first step to elucidating this important question has been taken by Hull (9) who demonstrated a rapid exchange of [1 ^{14}C]palmitate from the mother to the fetus In contrast to the present study Fosbrooke & Wharton (7) found significantly higher cord plasma triglyceride in full term than in preterm newborns

As for total cholesterol Rafstedt (10) has previously reported that cord plasma total cholesterol concentration was the same in infants with a birth weight below and above 2 500 g However he did not assess the gestational age of the infants and thus did not differentiate between AGA and SGA infants

Fosbrooke & Wharton (7) did not find any

GONADOTROPIN RELEASING HORMONE (LH RH) AND HUMAN CHORIONIC GONADOTROPIN IN THE TREATMENT OF TWO BOYS WITH HYPOGONADOTROPHIC HYPOGONADISM

S KRABBE and N E SKAKKEBÆK

From Childrens Hospital Fuglebakken University Department of Paediatrics and Laboratory of Reproductive Biology University Department of Obstetrics & Gynaecology Rigshospitalet Copenhagen Denmark

ABSTRACT Krabbe S and Skakkebæk N E (Childrens Hospital Fuglebakken University Department of Paediatrics and Laboratory of Reproductive Biology University Department of Obstetrics & Gynaecology Rigshospitalet Copenhagen Denmark) Gonadotropin releasing hormone (LH RH) and human chorionic gonadotropin in the treatment of two boys with hypogonadotrophic hypogonadism Acta Paediatr Scand 66 361 1977.—Two brothers 16 and 14 years of age with hypogonadotrophic hypogonadism and anosmia were treated with subcutaneous injections of 200 μg gonadotropin-releasing hormone at 8-hour intervals for 4 weeks Serum FSH increased to the range of normal adult men but serum LH and serum testosterone showed little change and no clinical signs of pubertal development occurred Thereafter the 2 patients were given HCG for 11 months and a combination of HCG and HMG for a further 3 months In response to this treatment the serum testosterone levels increased to the range of normal adult men and a marked development of the secondary sex characteristics was seen

KEY WORDS Male hypogonadotrophic hypogonadism gonadotropin releasing hormone human chorionic gonadotropin

Hypogonadotrophic hypogonadism in association with hyposmia or anosmia is known as Kallman s syndrome (11 17) The basic hormonal defect of this type of hypogonadism seems to be the lack of a normal production of the gonadotropin releasing hormone (1 7 11 13 19) Administration of this hormone would thus appear to be a rational therapy Some reports are available concerning a variable effect of prolonged LH RH administration (7 8 10 18 19) Mortimer et al (10) have concluded that continuous treatment with LH RH may induce puberty in prepubertal boys

We have compared LH RH treatment with a combination therapy of HCG (human chorionic gonadotropin) and HMG (human menopausal gonadotropin) in two brothers with hypogonadotrophic hypogonadism and anosmia

PATIENTS

Case I

A 16-year-old boy was referred to the clinic on a count of failure of pubertal development The testes were not present in the scrotum at birth and remained undescended A trial with HCG had been made for 6 weeks at the age of 6 years but the gonads did not descend Orchidopexy was then performed on the right and on the left side at the age of 9 and 10 years respectively

On admission the boy was found to be 171 cm in height but was thin and infantile with no signs of puberty The penis was small the right testis was located in the inguinal canal and the left testis in the scrotum and both measured 1 cm

Otoneurological examination revealed total anosmia Bone age was 13 years 3 months X ray of sella turcica was normal TSH plasma cortisol and the chromosome complement were normal Serum FSH was low and serum LH unmeasurable A test dose of 100 μg of LH RH given intravenously gave a pituitary response with a threefold increase in FSH and an increase in LH from undetectable to barely detectable levels as shown in Table I Biopsy from the scrotal testis showed no signs of activity of the Leydig-cells and spermatogenesis was not initiated although gonocytes were present

difference in cord plasma total cholesterol concentration in AGA infants above (mean 2 52 mmol/l) and in AGA infants below (mean 2 50 mmol/l) 37 weeks of gestation

In contrast Šabata (11) found significantly higher total cholesterol values in umbilical vein blood in prematures weighing 2000–2500 g (mean 4 07 mmol/l) compared to full term newborns (mean 2 10 mmol/l)

To our knowledge this study is the first presentation of lipoprotein cholesterol values in AGA infants born before the 37th week of gestation Assuming that circulating LDL cholesterol is a storage depot of liver cholesterol as suggested by Brown & Goldstein (12) the higher values of LDL cholesterol in these infants might indicate that the need for LDL cholesterol produced by the liver and transported to peripheral tissues for membrane and hormone synthesis may be higher between the 33th–37th week of gestation than at term

Whether the higher values of HDL cholesterol in cord serum of betamethasone treated infants does reflect an increased synthesis of phospholipids which are also transported in the HDL molecules remains to be answered

40	12 7	2 7	13 1	3 0
60	12 1	2 5	14 2	3 0

Case II

The 14 year-old brother of case 1 also referred to the clinic because of infantilism At the age of 8 years he was treated with HCG for cryptorchidism without success and orchidopexy on both sides was performed

On admission he was found to be 161 cm in height and had normal body proportions He was infantile with no signs of puberty Both testes measured 1 cm³ and were located in the scrotum

Otoneurological examination revealed total anosmia Bone age was 12 years and 6 months X ray of sella turcica was normal TSH plasma cortisol and the chromosome complement were normal The LH RH test showed a response similar to that of his brother (Table 1) Testicular biopsy showed no signs of activity of the Leydig cells and spermatogenesis was not initiated although gonocytes were present

METHODS

LH RH treatment

Both patients were given subcutaneous injections of 200 µg of LH RH at intervals of 8 hours for 4 weeks Blood specimens of peripheral venous blood were taken repeatedly as shown in Figs 1 and 2 All samples were analysed for FSH LH and testosterone In order to evaluate a possible long term effect the same analyses were carried out 10 weeks after the conclusion of treatment

HCG HMG treatment

Five months after withdrawal of LH RH therapy both boys were given a dose of 3 000 i u of HCG three times weekly administered as intramuscular injections Two months after this treatment was initiated both patients unexpectedly stopped taking the injections for 2 weeks because of fear of a too rapid pubertal development The regime was therefore continued with a HCG-dose of 3 000 i u twice weekly HCG was given alone for 11 months then HMG was added in a dose of 150 units three times weekly for 3 months and during that period the HCG dose was reduced to 1 500 i u three times weekly All treatment was then discontinued During the treatment regular clinical evaluations were performed and blood specimens for analysis of testosterone were taken once a month

Hormone assays

Serum FSH and LH were measured by specific radioimmuno assays (Statens Seruminstitut Copenhagen) The results are expressed in terms of the second international reference preparation of human menopausal gonadotropin (2nd IRP HMG per l serum) LER 907 (NIH) was used as standard preparation In these assays 1 mg LER 907 is equivalent to 200 i u 2nd IRP HMG of LH and 33 i u 2nd IRP HMG of FSH respectively (14)

Serum testosterone was measured by radioimmuno assay including thin layer chromatography (1?) (Medicinsk Laboratorium Copenhagen)

RESULTS

LH RH treatment

The variations in FSH LH and testosterone during treatment of both patients with LH RH are shown in Figs 1 2 and 3 Generally there was considerable fluctuation The levels of FSH showed a threefold increase during the first and the eighth day of therapy and in both patients all peak values were within the range of untreated normal adult men (14) The increment increased from the first to the eighth day after which no further increase was seen

The levels of LH were low during all 4 weeks In the first patient LH increased during the first day from undetectable to barely detectable levels thus implying a response

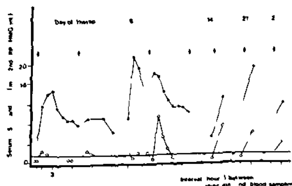

Fig 1 Serum FSH and serum LH values during daily treatment with LH RH given subcutaneously at 8 hour intervals for 28 days in a patient with hypogonadotrophic hypogonadism and anosmia (case I) *N D = not detectable*

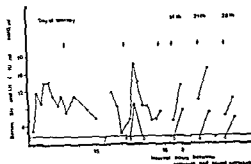

Fig 2 Serum FSH and serum LH values during daily treatment with LH RH given subcutaneously at 8 hour intervals for 28 days in a patient with hypogonadotrophic hypogonadism and anosmia (case II) N D =not detectable

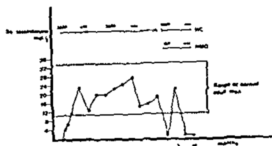

Fig 4 Serum testosterone values during combined HCG HMG treatment for 14 months in a patient with hypogonadotrophic hypogonadism and anosmia (case I)

within the prepubertal range (4 7) A further small increase was seen during the following days In the second patient LH remained undetectable during the first day but otherwise the responses were mostly similar to those of the first patient Both LH and FSH fell to very low levels shortly after the LH RH injections

Also the serum testosterone levels remained very low as shown in Fig 3 The serum testosterone value increased only slightly after injection of LH RH and in both cases the serum testosterone level was below the range found in early puberty in boys (2)

No change in the secondary sex characteristics was observed during the LH RH treatment

HCG HMG treatment

The serum testosterone concentrations during treatment with HCG and HMG are shown in Figs 4 and 5 Approximately 4 weeks after initiation of treatment the testosterone levels in both patients reached the lower limit of the range of normal adult men A marked drop in serum testosterone was found when treatment was withdrawn Normal adult levels of testosterone were obtained after resuming the regime although the dose of HCG given was smaller Four weeks after termination of treatment the serum testosterone values were similar to those found in normal prepubertal boys

Wide variations in serum testosterone were seen during the last 3 months of treatment We offer no explanation for this phenomenon but since the half lives of HCG and testosterone are short (6 17) even minor irregularities in

Case II

The 14 year-old brother of case I also referred to the clinic because of infantilism At the age of 8 years he was treated with HCG for cryptorchidism without success and orchidopexy on both sides was performed

On admission he was found to be 161 cm in height and had normal body proportions He was infantile with no signs of puberty Both testes measured 1 cm³ and were located in the scrotum

Otoneurological examination revealed total anosmia Bone age was 12 years and 6 months X ray of sella turcica was normal TSH plasma cortisol and the chromosome complement were normal The LH RH test showed a response similar to that of his brother (Table 1) Testicular biopsy showed no signs of activity of the Leydig cells and spermatogenesis was not initiated although gonocytes were present

METHODS

LH RH treatment

Both patients were given subcutaneous injections of 200 µg of LH RH at intervals of 8 hours for 4 weeks Blood specimens of peripheral venous blood were taken repeatedly as shown in Figs 1 and 2 All samples were analysed for FSH LH and testosterone In order to evaluate a possible long term effect the same analyses were carried out 10 weeks after the conclusion of treatment

HCG HMG treatment

Five months after withdrawal of LH RH therapy both boys were given a dose of 3 000 i u of HCG three times weekly administered as intramuscular injections Two months after this treatment was initiated both patients unexpectedly stopped taking the injections for 2 weeks because of fear of a too rapid pubertal development The regime was therefore continued with a HCG-dose of 3 000 i u twice weekly HCG was given alone for 11 months then HMG was added in a dose of 150 units three times weekly for 3 months and during that period the HCG dose was reduced to 1 500 i u three times weekly All treatment was then discontinued During the treatment regular clinical evaluations were performed and blood specimens for analysis of testosterone were taken once a month

Hormone assays

Serum FSH and LH were measured by specific radioimmuno assays (Statens Seruminstitut Copenhagen) The results are expressed in terms of the second international reference preparation of human menopausal gonadotropin (2nd IRP HMG per l serum) LER 907 (NIH) was used as standard preparation In these assays 1 mg LER 907 is equivalent to 200 i u 2nd IRP HMG of LH and 33 i u 2nd IRP HMG of FSH respectively (14)

Serum testosterone was measured by radioimmuno assay including thin layer chromatography (12) (Medicinsk Laboratorium Copenhagen)

RESULTS

LH RH treatment

The variations in FSH LH and testosterone during treatment of both patients with LH RH are shown in Figs 1 2 and 3 Generally there was considerable fluctuation The levels of FSH showed a threefold increase during the first and the eighth day of therapy and in both patients all peak values were within the range of untreated normal adult men (14) The increment increased from the first to the eighth day after which no further increase was seen

The levels of LH were low during all 4 weeks In the first patient LH increased during the first day from undetectable to barely detectable levels thus implying a response

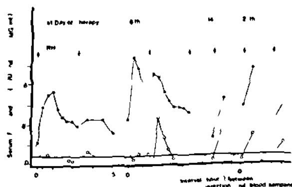

Fig 1 Serum FSH and serum LH values during daily treatment with *LH RH given subcutaneously at 8 hour* intervals for 28 days in a patient with hypogonadotrophic hypogonadism and anosmia (case I) N D =not detectable

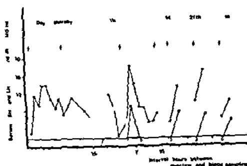

Fig 2 Serum FSH and serum LH values during daily treatment with LH RH given subcutaneously at 8 hour intervals for 28 days in a patient with hypogonadotrophic hypogonadism and anosmia (case II) N D = not detectable

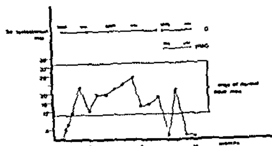

Fig 4 Serum testosterone values during combined HCG HMG treatment for 14 months in a patient with hypogonadotrophic hypogonadism and anosmia (case I)

within the prepubertal range (4 7) A further small increase was seen during the following days In the second patient LH remained undetectable during the first day but otherwise the responses were mostly similar to those of the first patient Both LH and FSH fell to very low levels shortly after the LH RH injections

Also the serum testosterone levels remained very low as shown in Fig 3 The serum testosterone value increased only slightly after injection of LH RH and in both cases the serum testosterone level was below the range found in early puberty in boys (2)

No change in the secondary sex characteristics was observed during the LH RH treatment

HCG HMG treatment

The serum testosterone concentrations during treatment with HCG and HMG are shown in Figs 4 and 5 Approximately 4 weeks after initiation of treatment the testosterone levels in both patients reached the lower limit of the range of normal adult men A marked drop in serum testosterone was found when treatment was withdrawn Normal adult levels of testosterone were obtained after resuming the regime although the dose of HCG given was smaller Four weeks after termination of treatment the serum testosterone values were similar to those found in normal prepubertal boys

Wide variations in serum testosterone were seen during the last 3 months of treatment We offer no explanation for this phenomenon but since the half lives of HCG and testosterone are short (6 17) even minor irregularities in

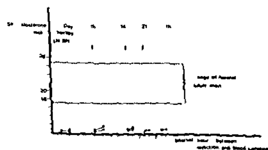

Fig 3 Serum testosterone values during daily treatment with LH RH given subcutaneously at 8 hour intervals for 28 days in two patients with hypogonadotrophic hypogonadism and anosmia O—O case I ●—● case II

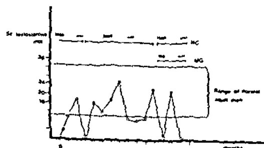

Fig 5 Serum testosterone values during combined HCG HMG treatment for 14 months in a patient with hypogonadotrophic hypogonadism and anosmia (case II)

the time of injection may cause considerable fluctuations in serum testosterone

Clinical marked development of the secondary sex characteristics was seen during the course of treatment Both boys reached a pubertal stage of grade IV (16) When the treatment was terminated in case I the right and left testis measured 6 and 3 ml, respectively, whereas the testicular volume increased to 3 ml on both sides in case II Both patients eventually experienced frequent erection and ejaculations, especially during the last 3 months Six weeks after the end of treatment it was not possible for the first patient to have ejaculation and the other had a small ejaculate

DISCUSSION

The findings in the present study support the theory that hypogonadotrophic hypogonadism may be caused by a primary hypothalamic defect involving a defective release or impaired synthesis of the gonadotropin releasing hormone These results are at variance with those of Mortimer et al (10) who concluded that long term treatment with LH RH may constitute an effective means of treating patients with hypogonadotrophic hypogonadism However the dose of LH RH and the period of treatment are not comparable in the two studies, which may account for the difference in the results Mortimer and co workers used a dose of 500 μg LH RH given as subcutanous injections at 8 hour intervals for 4 to 20 weeks in the prepubertal patients The administration of LH RH in our patients resulted in a release of gonatropins from the pituitary but this treatment did not induce serum levels of FSH and LH sufficient to stimulate the testes to produce adequate amounts of testosterone It is possible that the administration of LH RH over a longer period of time and/or in larger doses would have initiated puberty in our patients However the necessity of frequent injections made it impossible to continue administration of the hormone A recent report of a LH RH analogue with effect after oral administration is of great interest (5)

Patients with hypogonadotrophic hypogonadism usually show good testicular response to exogenous gonadotropins, though Bardin et al (3) reported that the response of some patients to HCG was poor Our patients showed testicular response with serum testosterone levels in the normal adult range and a marked development of secondary sex characteristics during the HCG HMG treatment

To conclude we failed to induce a significant increase in serum testosterone levels by 8 hourly subcutaneous injections of 200 μg LH RH for 4 weeks in two boys with hypogonadotrophic hypogonadism although both patients showed some response to LH RH by an increase in serum FSH and serum LH Further development of orally active or long acting injectable LH RH would seem to be essential if this hormone is to be used in the treatment of male hypogonadotrophic hypogonadism

ACKNOWLEDGEMENT

The LH RH was kindly supplied by Hoechst The study was supported by a grant from the Danish Medical Research Council to N E S (512 5881)

MEASLES AS A CAUSE OF FETAL DEFECTS

A Retrospective Study of Ten Measles Epidemics in Greenland

CARSTEN SAND JESPERSEN JØRGEN LITTAUER and UFFE SAGILD

From Dronning Ingrids Hospital Medical Department Godthaab Greenland

ABSTRACT Sand Jespersen C Littauer J and Sagild U (Dronning Ingrids Hospital Godthaab Greenland) Measles as a cause of fetal defects A retrospective study of ten measles epidemics in Greenland Acta Paediatr Scand 66 367 1977 —In a retrospective study of ten epidemics of measles in virgin-soil populations in Greenland 368 women were found to be pregnant at the time of their infection with measles Information on the course of the pregnancies was obtained in 327 of these women and a clinical examination was made of 252 of their children The risk of fetal death among women infected in the first trimester was found to be high About half of 20 women infected during their first two months of pregnancy and a fifth of 31 women infected in the third month had abortions 9% of 64 women infected in the first trimester and going to term had stillbirths 28 women infected in the first two months of pregnancy had live children but four of these had congenital malformations three of extreme rarity and severity leading to death The rate of perinatal mortality and prematurity was equal among infants exposed to measles in the first second and third trimester of fetal life

KEY WORDS Measles fetal defects fetal death congenital malformations perinatal mortality prematurity Greenland

Since Gregg s epoch making report in 1941 (5) on the association between maternal rubella and fetal defects several reports on the possible effects of viral infections on fetal development have appeared The effect of measles on fetuses during early pregnancy has also been studied but the number of cases was too small to allow definite conclusions to be drawn (9 10) As the disease is very rare in the child bearing population of urban communities so called virgin soil populations have been the only source from which an adequate number of infected pregnant women could be obtained An early report on an epidemic of measles in South Greenland (3) suggested a significantly increased abortion rate in women infected early in pregnancy Later in a study of 155 pregnant women infected with measles during different epidemics in Greenland we suggested that measles in the first trimester of pregnancy involves a risk for the fetus probably comparable to that previously observed for rubella (7)

The present report concerns a retrospective study of the outcome of 327 women infected with measles The cases are collected from all registered epidemics of measles in virgin soil populations in Greenland—all occurring in the period 1951–1962 The 155 pregnancies reported previously are included

Four aspects of measles in pregnancy have been studied 1) Rate of fetal death 2) incidence of congenital defects in live born infants 3) infant mortality and 4) rate of prematurity

MATERIAL AND METHODS

During most epidemics of measles in Greenland individual patient records were kept by local physicians In addition detailed overall reports concerning the course of

each epidemic and its effects on individual communities were submitted by local medical personnel to the central health authorities in Greenland (1 2 4)

In the majority of cases diagnoses were made by local physicians although in some areas specially trained nurses constituted the only medical authority available The diagnosis of measles was never in doubt in the reported group of patients

In Greenland all deliveries are registered in the local hospitals In addition it is customary to admit all cases with a history of suspected or verified abortion in the second month of gestation or later By studying this material we were able to indentify all women having an abortion or a delivery during the period from the beginning of each of the epidemics until 40 weeks after their termination

The date of conception calculated from the recorded date of expected delivery or the last menstrual period was compared with the date of appearance of the measles rash in each case and a number of women presumably infected before conception were indentified and excluded from the material A number of women who were infected after delivery were similarly excluded In this way we obtained a group of 368 women infected with measles during pregnancy who with the addition of a presumably small group on non registered cases of abortion (to be discussed later) would constitute all pregnant women infected during the epidemics mentioned (Table 1)

An attempt was made to localize and to contact all these women but in 41 cases we were unsuccessful because of deficient registers Thus the outcome of these pregnancies is unknown

Of the remaining 327 women 61 were not contacted by us because in addition to their living in geographical areas difficult to approach evidence was available to indicate that these women had either had an abortion or the exposed child had died at birth or later In the latter cases the causes of death were ascertained as far as possible through death certificates or in some cases through hospital records

All the remaining 266 women were contacted by one of us at which time the women s recollections regarding their measles infections and the course of their pregnancies were checked against previously obtained information

At the same time all surviving children exposed to measles during their intrauterine life 252 in all were examined

These children whose age at the time of the study varied between one and sixteen years underwent a general clinical examination including measurements of weight and height and in 150 cases standard electrocardiographic tracings were obtained Included in this group are all cases with cardiac murmurs or other signs of congenital heart disease In the remaining 10[?] cases with no suspicion of heart disease mainly living in remote areas with no access to electrocardiographic equipment it was considered that practical difficulties prohibited the taking of tracings

X ray studies of the chest were obtained in all cases of suspected cardiac disease In addition all X ray records obtained during previous annual check ups for tuberculosis (attended by practically all of the population were screened for evidence of cardiovascular disease

Finally to check the possible presence of congenital hearing defects all children aged twelve years or more at the time of the study (104 in all) were subjected to audiometric tests Circumstances did not permit the use of sound insulated rooms A hearing loss was considered to be present if the audiogram showed a loss of more than 2[?] db at one or more frequencies in one or both ears

RESULTS

1 *Rate of fetal death*

The rate of abortion by week of gestation at the time of the measles infection is shown in Table 2 The table includes only 214 pregnancies because hospital records of abortions during the relevant period in four epidemic areas could not be located and may have been discarded (cf note to Table 1) The table includes 51 cases of women at risk of abortion infected in the first trimester and 76 in the second It appears that about 30% infected in the first trimester had abortions while among those infected in the second trimester only 4% of the cases had abortions

Despite the uncertainty in relating the date of infection to the date of conception very early in pregnancy we believe that the data

Table 2 *Rate of abortion by week of gestation at time of infect on*

Fetal age at time of infection (weeks)	No of infected mothers	Abortions	
		No	%
1–4	6	4	67
5–8	14	6	43
9–13	31	6	19
1st trimester total	51	16	32
14–26	76	3	4
27–40	87		
Total	214	19	9

In tables 2 3 4 5 and 6 fetal age is derived from the calculated date of conception

Table 3 *Rate of stillbirth in relation to fetal age at time of measles infection*

Fetal age at time of infection (weeks)	No of children from non aborting infected mothers	Stillbirths	
		No	%
1–4	6	0	0
5–8	17	0	0
9–13	41	6	15
1st trimester total	64	6	9
14–26	114	3	3
27–40	133	2	2
Total	311	11	3

Including two pairs of twins

suggest the risk of abortion is greatest when the mother is infected in the first part of the first trimester and is probably about 50%

Table 3 shows the rate of stillbirth in relation to the fetal age at the time of infection With increasing fetal age at the time of infection the risk of stillbirth decreases but the difference between groups is not great It is noteworthy however that the women infected in the first two months despite high abortion risks did not have stillbirths

2 *Congenital malformations*

Table 4 lists eight cases of gross congenital malformations previously diagnosed among 300 liveborn infants

Among 58 infants with mothers infected in the first trimester five cases were found (9%) Three of these five died before the age of ten months by causes directly attributable to their defects These three infants were afflicted with malformations of extreme rarity One had an atypical cerebral leucodystrophy with dysplasia particularly in the right hemisphere the second was a cyclop with *microcephaly* and polydactyli and the third infant had *multiple* cardiac anomalies atrial septal defect atrophic right ventricel communicating through a ventricular septal defect with a hypertrophic left ventricle and a hypertrophic aorta total atresia of the tricuspid valve and *stenosis of* the pulmonary valve The other two children survived with defects of less rarity and severity (anal atresia and harelip)

Among 111 children of mothers infected in their second trimester of pregnancy there were two cases of known or presumed congenital malformations (spastic tetraplegia stenosis of pulmonary artery) Both children are alive

Finally among 131 children whose mothers

Table 4 *Congenital malformations among 300 liveborn infants*[a]

Case no	Sex	Fetal age at time of infection (month)	Diagnosis	Course
1	f	First	Atypical leucodystrophy of brain	Dead 10 weeks
2	f	Second	Cyclopia	Dead ? hours
3	m	Second	Multiple cardiac anomalies	Dead 10 months
4	m	Second	Anal atresia	Alive
5	f	Third	Cheilo-gnato palato-schisis	Alive
6	m	Fourth	Spastic tetraplegia	Alive
7	m	Fifth	Stenosis of pulm artery	Alive
8	f	Eight	Patent duct arteriosus	Alive

each epidemic and its effects on individual communities were submitted by local medical personnel to the central health authorities in Greenland (1 2 4)

In the majority of cases diagnoses were made by local physicians although in some areas specially trained nurses constituted the only medical authority available The diagnosis of measles was never in doubt in the reported group of patients

In Greenland all deliveries are registered in the local hospitals In addition it is customary to admit all cases with a history of suspected or verified abortion in the second month of gestation or later By studying this material we were able to indentify all women having an abortion or a delivery during the period from the beginning of each of the epidemics until 40 weeks after their termination

The date of conception calculated from the recorded date of expected delivery or the last menstrual period was compared with the date of appearance of the measles rash in each case and a number of women presumably infected before conception were indentified and excluded from the material A number of women who were infected after delivery were similarly excluded In this way we obtained a group of 368 women infected with measles during pregnancy who with the addition of a presumably small group on non registered cases of abortion (to be discussed later) would constitute all pregnant women infected during the epidemics mentioned (Table 1)

An attempt was made to localize and to contact all these women but in 41 cases we were unsuccessful because of deficient registers Thus the outcome of these pregnancies is unknown

Of the remaining 327 women 61 were not contacted by us because in addition to their living in geographical areas difficult to approach evidence was available to indicate that these women had either had an abortion or the exposed child had died at birth or later In the latter cases the causes of death were ascertained as far as possible through death certificates or in some cases through hospital records

All the remaining 266 women were contacted by one of us at which time the women s recollections regarding their measles infections and the course of their pregnancies were checked against previously obtained information

At the same time all surviving children exposed to measles during their intrauterine life 252 in all were examined

These children whose age at the time of the study varied between one and sixteen years underwent a general clinical examination including measurements of weight and height and in 150 cases standard electrocardiographic tracings were obtained Included in this group are all cases with cardiac murmurs or other signs of congenital heart disease In the remaining 102 cases with no suspicion of heart disease mainly living in remote areas with no access to electrocardiographic equipment it was considered that practical difficulties prohibited the taking of tracings

X ray studies of the chest were obtained in all cases of suspected cardiac disease In addition all X ray records obtained during previous annual check ups for tuberculosis (attended by practically all of the population) were screened for evidence of cardiovascular disease

Finally to check the possible presence of congenital hearing defects all children aged twelve years or more at the time of the study (104 in all) were subjected to audiometric tests Circumstances did not permit the use of sound insulated rooms A hearing loss was considered to be present if the audiogram showed a loss of more than 20 db at one or more frequencies in one or both ears

RESULTS

1 *Rate of fetal death*

The rate of abortion by week of gestation at the time of the measles infection is shown in Table 2 The table includes only 214 pregnancies because hospital records of abortions during the relevant period in four epidemic areas could not be located and may have been discarded (cf note to Table 1) The table includes 51 cases of women at risk of abortion infected in the first trimester and 76 in the second It appears that about 30% infected in the first trimester had abortions while among those infected in the second trimester only 4% of the cases had abortions

Despite the uncertainty in relating the date of infection to the date of conception very early in pregnancy we believe that the data

Table 2 *Rate of abortion by week of gestation at time of infection*

Fetal age at time of infection (weeks)	No of infected mothers	Abortions	
		No	%
1– 4	6	4	67
5– 8	14	6	43
9–13	31	6	19
1st trimester total	51	16	32
14–26	76	3	4
27–40	87		
Total	214	19	9

In tables 2 3 4 5 and 6 fetal age is derived from the calculated date of conception

Table 3 *Rate of stillbirth in relation to fetal age at time of measles infection*

Fetal age at time of infection (weeks)	No of children from non aborting infected mothers	Stillbirths	
		No	%
1– 4	6	0	0
5– 8	17	0	0
9–13	41	6	15

27–40	133	2	2
Total	311	11	3

Including two pairs of twins

suggest the risk of abortion is greatest when the mother is infected in the first part of the first trimester and is probably about 50%

Table 3 shows the rate of stillbirth in relation to the fetal age at the time of infection With increasing fetal age at the time of infection the risk of stillbirth decreases but the difference between groups is not great It is noteworthy however that the women infected in the first two months despite high abortion risks did not have stillbirths

2 *Congenital malformations*

Table 4 lists eight cases of gross congenital malformations previously diagnosed among 300 liveborn infants

Among 58 infants with mothers infected in the first trimester five cases were found (9%) Three of these five died before the age of ten months by causes directly attributable to their defects These three infants were afflicted with malformations of extreme rarity One had an atypical cerebral leucodystrophy with dysplasia particularly in the right hemisphere the second was a cyclop with microcephaly and polydactyli and the third infant had multiple cardiac anomalies atrial septal defect atrophic right ventricel communicating through a ventricular septal defect with a hypertrophic left ventricle and a hypertrophic aorta total atresia of the tricuspid valve and stenosis of the pulmonary valve The other two children survived with defects of less rarity and severity (anal atresia and harelip)

Among 111 children of mothers infected in their second trimester of pregnancy there were two cases of known or presumed congenital malformations (spastic tetraplegia stenosis of pulmonary artery) Both children are alive

Finally among 131 children whose mothers

Table 4 *Congenital malformations among 300 liveborn infants*

Case no	Sex	Fetal age at time of infection (month)	Diagnosis	Course
1	f	First	Atypical leucodystrophy of brain	Dead 10 weeks
2	f	Second	Cyclopia	Dead 2 hours
3	m	Second	Multiple cardiac anomalies	Dead 10 months

RESULTS

1 *Rate of fetal death*

The rate of abortion by week of gestation at the time of the measles infection is shown in Table 2 The table includes only 214 preg nancies *because hospital records of* abor tions during the relevant period in four epidemic areas could not be located and may have been discarded (cf note to Table 1) The table includes 51 cases of women at risk of abortion infected in the first trimester and 76 in the second It appears that about 30% infected in *the first trimester had abortions* while among those infected in the second trimester only 4% of the cases had abortions

Despite the uncertainty in relating the date of infection to the date of conception very early in pregnancy we believe that the data

the rapidly increasing development of com munications with previously virgin soil pop ulations it is not likely that opportunities for prospective studies of groups of similar size will arise

The difficulties inherent in the acquisition of valid data on fetal death early in pregnancy are obvious (10) Women are usually not seen for prenatal care until late in the first trimester and some cases of abortions may pass unrec ognized or remain unreported Thus exact figures demonstrating the increased risk of abortion following infection with measles in early pregnancy are difficult to obtain

In the present paper there is a considerable difference between the numbers of women pregnant in the first second and third trimes ter at the time of infection and in the first trimester between the numbers of those in fected in the first second and third month of gestation (Tables 2 3 5 6) Possibly the pres ence of an epidemic in a community may reduce the number of conceptions during this period Furthermore the method used in this paper to calculate the dates of conception and infection may have resulted in the exclusion of some women because this calculation errone ously indicated the date of infection before the date of conception We thus believe that the data for the rates of abortion shown in Table 2 represent minimum figures

The risk of fetal death among women in fected in the first trimester is high Half of the women infected in the first two months of ges tation and one out of five of those infected in the third month had abortions Among the re maining women going to term one in seven had a dead child

23 women infected with measles in the first two months of pregnancy gave birth to live children but four of these had congenital malformations Three of the congenital defects were of extreme rarity and severity leading directly to death It is hardly conceivable that the measles infection as such was not a domi nant etiological factor in these cases of con genital malformations

The remaining four of the eight cases of congenital malformations found in the total group of 300 children were of much more common types and the children were born by mothers infected later in pregnancy As the incidence of congenital malformations in Greenland is known to be high (6) the measles infection may not have been an etiological factor in these cases The audiometric tests revealed abnormal hearing in about 25% of the children examined In most of these cases this could be attributed to previous middle ear infection which is known to be a common cause of hearing defects in Greenland (8) We believe that our data on the remaining children are too sparse to allow conclusions regarding the etiology of the hearing loss

The perinatal mortality figures are more dif ficult to interpret We did not as expected find any significantly higher perinatal mortal ity among children exposed to measles early in fetal life but the mortality among the liveborn infants as a whole irrespective of the time of exposure to measles was higher than normal in Greenland (about 10% versus approx 7%) (11) Information on the causes of death of the 32 children dying in the first year of life is fragmentary Possibly the high mortality among those infected early in fetal life may partly be due to a decreased viability caused by the maternal infection while the high mor tality among those exposed towards the end of gestation may be due to external factors in the environment into which they were born We know of a few cases of early death attributed to the mother being sick with measles or com plications thereof at the time of delivery

Regarding prematurity the findings were similar There was no significant difference in the rate of prematurity between the groups of children exposed in the first second or third trimester but the rate of prematurity as a whole was somewhat higher than is usual in Greenland (4) Again it is conceivable that some children exposed to measles in the first part of their intrauterine life were small at birth because of some inherent damage caused by

Table 5 *Infant mortality in relation to fetal age at time of maternal measles infection*

Fetal age at time of infection (weeks)	No of liveborn infants	Infant mortality during first year of life	
		No	%
1–4	5	2	40
5–8	14	2	14
9–13	34	2	5
1st trimester total	53	6	11
14–26	107	10	9
27–40	126	16	13
Total	286	32	12

were infected in their third trimester of pregnancy, only one child with a congenital malformation a case of patient ductus arteriosus was diagnosed The diagnosis was verified in a successfully performed operation

Among 252 children exposed to measles during their intrauterine life no further cases with definite evidence of congenital malformations were found 27 children were found to have cardiac murmurs which were however soft and systolic in character all had normal electrocardiograms and chest X rays and none had symptoms suggesting cardiac disease Electrocardiographic abnormalities were found in five children without any associated signs or symptoms of cardiac disease One child had a complete right bundle branch block (RBB) two had incomplete RBB and one had a grade one a v block

Audiometric tests revealed abnormal hearing in 27 cases of 104 studied In 17 instances the hearing loss could be attributed to previous middle ear infection Among the remaining ten seven had significant hearing loss only at high frequencies (8 000 Hz or 4 000+8 000 Hz) Finally three children whose mothers were infected by measles during their 4th 5th and 9th month respectively had bilateral diffuse hearing loss of about 40–50 db

3 *Infant mortality*

Table 5 relates the infant mortality to the stage of gestation at the time of the maternal infection From the total group of 300 liveborn infants we have excluded the previously mentioned 8 cases of established congenital malformations and three pairs of twins In fact, two of the eight children with congenital malformations and two pairs of the twins died during their first year of life

Although the data might suggest a decreased viability among those exposed to measles early during their intrauterine life the figures are too small to allow any definite conclusions

4 *Rate of prematurity*

Information on the birth weights of 231 infants exposed to maternal measles was available Two pairs of twins have been excluded from this group The birth weight in relation to the stage of gestation at the time of the maternal infection is shown in Table 6 26 children (11%) had birth weights below 2 500 grams The birth weight appears to be uninfluenced by the stage of gestation at the time of infection

DISCUSSION

The present study was conducted retrospectively which imposes obvious drawbacks compared to the prospective method It is however by far the largest group of measles infected pregnant women reported and with

Table 6 *Low birth weight of liveborn infants in relation to fetal age at time of maternal measles infection*[a]

[a] Children with congenital defects and two pairs of twins have been excluded

the rapidly increasing development of communications with previously virgin soil populations it is not likely that opportunities for prospective studies of groups of similar size will arise

The difficulties inherent in the acquisition of valid data on fetal death early in pregnancy are obvious (10) Women are usually not seen for prenatal care until late in the first trimester and some cases of abortions may pass unrecognized or remain unreported Thus exact figures demonstrating the increased risk of abortion following infection with measles in early pregnancy are difficult to obtain

In the present paper there is a considerable difference between the numbers of women pregnant in the first second and third trimester at the time of infection and in the first trimester between the numbers of those infected in the first second and third month of gestation (Tables 2 3 5 6) Possibly the presence of an epidemic in a community may reduce the number of conceptions during this period Furthermore the method used in this paper to calculate the dates of conception and infection may have resulted in the exclusion of some women because this calculation erroneously indicated the date of infection before the date of conception We thus believe that the data for the rates of abortion shown in Table 2 represent minimum figures

The risk of fetal death among women infected in the first trimester is high Half of the women infected in the first two months of gestation and one out of five of those infected in the third month had abortions Among the remaining women going to term one in seven had a dead child

23 women infected with measles in the first two months of pregnancy gave birth to live children but four of these had congenital malformations Three of the congenital defects were of extreme rarity and severity leading directly to death It is hardly conceivable that the measles infection as such was not a dominant etiological factor in these cases of congenital malformations

The remaining four of the eight cases of congenital malformations found in the total group of 300 children were of much more common types and the children were born by mothers infected later in pregnancy As the incidence of congenital malformations in Greenland is known to be high (6) the measles infection may not have been an etiological factor in these cases The audiometric tests revealed abnormal hearing in about 25% of the children examined In most of these cases this could be attributed to previous middle ear infection which is known to be a common cause of hearing defects in Greenland (8) We believe that our data on the remaining children are too sparse to allow conclusions regarding the etiology of the hearing loss

The perinatal mortality figures are more difficult to interpret We did not as expected find any significantly higher perinatal mortality among children exposed to measles early in fetal life but the mortality among the liveborn infants as a whole irrespective of the time of exposure to measles was higher than normal in Greenland (about 10% versus approx 7%) (11) Information on the causes of death of the 32 children dying in the first year of life is fragmentary Possibly the high mortality among those infected early in fetal life may partly be due to a decreased viability caused by the maternal infection while the high mortality among those exposed towards the end of gestation may be due to external factors in the environment into which they were born We know of a few cases of early death attributed to the mother being sick with measles or complications thereof at the time of delivery

Regarding prematurity the findings were similar There was no significant difference in the rate of prematurity between the groups of children exposed in the first second or third trimester but the rate of prematurity as a whole was somewhat higher than is usual in Greenland (4) Again it is conceivable that some children exposed to measles in the first part of their intrauterine life were small at birth because of some inherent damage caused by

the maternal infection while the children ex posed later in gestation were small because their mothers gave birth prematurely as a re sult of measles infection However we have no data to substantiate this point

ABSTRACT Gustavson K H Hagberg B Hagberg G and Sars K (Departments of Paediatrics Universities of Gothenburg Umeå and Uppsala) Severe mental retardation in a Swedish county I Epidemiology gestational age birth weight and associated CNS handicaps in children born 1959–70 Acta Paediatr Scand 66 373 1977.—In an unselected series of children born in 1959–70 with severe mental retardation (MR)—defined as IQ<50—in a Swedish county the incidence prevalence gestational length birth weight and associated CNS handicaps were analysed The cumulative incidence at 1–16 years of age was calculated at 3.3% and the prevalence at 11–16 years at 2 8‰ These figures were lower than in most other previous studies In the great majority of cases the pathogenesis was of prenatal origin The mean gestational lengths and birth weights were decreased compared with those of an average Swedish population Severe MR affected large and small for date babies more often than could be expected On the other hand babies with a low birth weight appropriate for gestational age and with an uncomplicated history were found not to run a special risk of severe MR Among the 122 children 42% had one or more associated CNS handicaps—epilepsy (30%) and cerebral palsy (18%) being the most common

KEY WORDS Severe mental retardation incidence prevalence birth weight associated CNS handicaps

In recent years doors have been opened for partial prevention of the birth of severely mentally retarded children Organized genetic counselling prenatal diagnosis of chromosomal aberrations hereditary biochemical disorders and neural tube defects vaccination of school girls against rubella and careful obstetric supervision of pregnancies at risk all together today ought to decrease the incidence of severe mental retardation (MR) (9) For comparative purposes in future epidemiological research it was thought to be of interest to sum up available data from severely mentally retarded children born in the period 1959–70 as this period may be considered to be the last one before the gradual introduction of prenatal prevention in Sweden and at the same time the period during which important peri and neonatal advances were documented (10)

This first part of the study deals with the incidence and prevalence of severe MR and the distribution according to sex gestational age birth weight and associated CNS handicaps

A second part will deal with the etiologic and pathogenetic aspects

MATERIALS AND METHODS

Definition

In this series severe mental retardation corresponds to an IQ<50 and present before the age of 18 years Apart from the most profoundly retarded children where the severity of their mental handicap was without doubt the children

the maternal infection while the children exposed later in gestation were small because their mothers gave birth prematurely as a result of measles infection However we have no data to substantiate this point

SEVERE MENTAL RETARDATION IN A SWEDISH COUNTY

I Epidemiology Gestational Age Birth Weight and Associated CNS Handicaps in Children Born 1959–70

K H GUSTAVSON B HAGBERG G HAGBERG and K SARS

From the Departments of Paediatrics Universities of Gothenburg Umea and Uppsala Sweden

ABSTRACT Gustavson K H Hagberg B Hagberg G and Sars K (Departments of Paediatrics Universities of Gothenburg Umeå and Uppsala) Severe mental retardation in a Swedish county I Epidemiology gestational age birth weight and associated CNS handicaps in children born 1959–70 Acta Paediatr Scand 66 373 1977.—In an unselected series of children born in 1959–70 with severe mental retardation (MR)—defined as IQ<50—in a Swedish county the incidence prevalence gestational length birth weight and associated CNS handicaps were analysed The cumulative incidence at 1–16 years of age was calculated at 3.3‰ and the prevalence at 11–16 years at 2.8‰ These figures were lower than in most other previous studies In the great majority of cases the pathogenesis was of prenatal origin The mean gestational lengths and birth weights were decreased compared with those of an average Swedish population Severe MR affected large and small for date babies more often than could be expected On the other hand babies with a low birth weight appropriate for gestational age and with an uncomplicated history were found not to run a special risk of severe MR Among the 122 children 42% had one or more associated CNS handicaps—epilepsy (30%) and cerebral palsy (18%) being the most common

KEY WORDS Severe mental retardation incidence prevalence birth weight associated CNS handicaps

In recent years doors have been opened for partial prevention of the birth of severely mentally retarded children Organized genetic counselling prenatal diagnosis of chromosomal aberrations hereditary biochemical disorders and neural tube defects vaccination of school girls against rubella and careful obstetric supervision of pregnancies at risk all together today ought to decrease the incidence of severe mental retardation (MR) (9) For comparative purposes in future epidemiological research it was thought to be of interest to sum up available data from severely mentally retarded children born in the period 1959–70 as this period may be considered to be the last one before the gradual introduction of prenatal prevention in Sweden and at the same time the period during which important peri and neonatal advances were documented (10)

This first part of the study deals with the incidence and prevalence of severe MR and the distribution according to sex gestational age birth weight and associated CNS handicaps

A second part will deal with the etiologic and pathogenetic aspects

MATERIALS AND METHODS

Definition

In this series severe mental retardation corresponds to an IQ<50 and present before the age of 18 years Apart from the most profoundly retarded children where the severity of their mental handicap was without doubt the children

Table 1 *Incidence of severe mental retardation in children aged 5–16 years born in the county of Uppsala Sweden in 1959–70 and alive at one year of age*

Birth year	Age	Number alive at one year of age	Severe mental retardation	
			n	‰
1959–64	11–16	16 779	55	3 28
1965–70	5–10	20 431	52	2 54
Total	5–16	37 210	107	2 88

had been given intelligence tests to determine suitability for education The tests used in most cases were the Terman–Merrill WISC and Merril-Palmer tests

Area investigated

The study covers a Swedish county the county of Uppsala with a population of slightly more than 200 000 inhabitants (1970) and of an average demographic structure There is one main central city Uppsala with a large teaching hospital and exceptionally good facilities for integrated neuropaediatric supervision and follow up of mentally retarded children

Search procedure

The object of the investigation was to trace every case of severe MR in children born 1959–70 in the county of Uppsala and alive at the age of one year This age restriction was made for two main reasons Firstly we considered it doubtful to retrospectively diagnose severe MR in a child who had died during its first year of life secondly the official statistics of Sweden give yearly the figures of live birth rates as well as the mortality during the first year of life

In each county of Sweden mentally retarded children are registered by a Board for Provisions and Services to the Mentally Retarded (BPSMR) (Omsorgsstyrelsen) with established laws and providing all sorts of support for daily life education training and habilitation Every child is dependent on being registered under this authority to get their full governmental and municipal support

As the present study was performed in 1975 the youngest children were at least 5 years old and it was highly probable that they all would be known by the above authority An examination was made of the register held by this authority for children born in 1959–70 in the county of Uppsala Children removed from the register because of death or migration were also noted Using the official ten digit registration number system alloted to everybody check ups were made in the registers of the same authorities in all other Swedish counties in order to trace those migrated before BPSMR registration but born in the Uppsala county The case records for MR at the departments of paediatrics and child psychiatry in Uppsala University Hospital for the years concerned were examined The death register at the departments of paediatrics the period 1960–75 was also scrutinized and those with established severe MR as well as with diagnoses known always to be connected with severe MR were included

The present series was considered complete due to the special medical insurance system in Sweden as well as the high degree of sociomedical organization and the well developed child health care system of this geographical area In addition since 1959 the medical service system for mentally retarded children has been centralized to Uppsala and intimately integrated with the neuropaediatric section of the department of paediatrics of the University Hospital

RESULTS AND CONCLUSIONS

A total of 122 children who were born in the county of Uppsala and satisfied the criteria of severe MR were traced The official registration of live births in Sweden is based on the mother s parish registration at the time of delivery Of the mothers 107 were registered in the county of Uppsala at the time of delivery and the number of children included in the incidence and prevalence calculations were therefore limited to 107 For the rest of the study all the 122 children were included

Incidence and prevalence

The investigation period 1959–70 was divided into the two periods 1959–64 and 1965–70 in order to study any changes in incidence The incidence of severely mentally retarded per 1 000 children alive at one year of age during the two periods is shown in Table 1 No statistically significant difference between the two periods was revealed The lower figure for 1965–70 may be accidental but it is more

Table 2 *Incidence of Down s syndrome among children live born in the county of Uppsala Sweden in 1959–70*

One child with IQ>50 included

Birth year	Number of live births	Down s syndrome	
		n	
1959–64	17 043	14	0 82
1965–70	20 689	19	0 92
Total	37 732	33	0 88
Including 40% dead during first year of life		55	1 46

Table 3 *Mean birth weight in different pathogenetic groups in a series of 122 children with severe MR born in 1959–70 FDS = Foetal deprivation of supply (7 11)*

Pathogenetic group	*n*	Mean birth weight (g)
Down s syndrome	39	3 106
Other genetic disorders	14	3 473
Other prenatal stigmata	24	3 795
Remaining patients with certain factors		
FDS	13	2 671
Asphyxia/cerebral haemorrhage	12	2 897
Cerebral palsy	17	2 794
Postnatal infections	4	2 688
Normal pre peri and postnatal history	17	3 437

probably explained by the true cumulative increase of the incidence of severe MR over the years of growth The term MR implies an ascertained diagnosis before the age of 16–18 years and it is a well known phenomenon that severely mentally retarded individuals show a progressive deterioration of test performance through the growing years (19 22) The true incidence of severe MR in our series was therefore considered to be representative of the children born 1959–64 aged 11–16 years and was 3 3 per 1 000 children alive at the age of one year

The number of deaths among the 122 mentally retarded children was 19 equally distributed over the two periods The median age at death was 3 years Only two children had died after 5 years of age The mortality rate thus amounted to 14% in the ages 1–5 years compared with 0 13% for the average population of the same ages in Sweden

As 16% of the mentally retarded children had died at the end of the follow up period (Dec 31 1975) the prevalence of severe MR at 11–16 years of age was calculated to be 2 8‰

Down s syndrome represented one third (39/122) of the total series and we thought it of interest to calculate its incidence per se As the mortality in Sweden for this syndrome during the first year of life is about 40% (12) the incidence was calculated on liveborns in the years concerned Table 2 shows that there was no significant difference between the two periods and that the calculated incidence figure of Down s syndrome per 1 000 live births was 1 46‰ This is quite in agreement with the findings in an earlier Swedish investigation (12) A lowering of the incidence to 1 32‰ during the years 1968–70 has been demonstrated in Sweden (15) Our figures do not contradict this decline which is probably due to the diminishing number of children born to women over 40 years of age Of the children with Down s syndrome only 3/39 (8%) died after their first year of life all between 1 and 5 years of age

The sex distribution

In the total series of 122 children 65 were boys and 57 girls giving a male excess ratio of 53 47 This sex difference is not significant

The children with Down s syndrome (39/122) showed a male excess ratio of 62 38 which is not statistically significant in this small series A significant male excess ratio has however been shown earlier in a larger Swedish series (15)

Birth weight

The mean birth weight in the total series was 3 173 g i e significantly ($p \leq 0$ 0001) lower than the mean (3 500) g in a normal Swedish population (13) 10 8% (14/122) had a low birth

Table 4 *The distribution of birth weight in relation to gestational age according to the Swedish standard curve in a series of 120 children with severe mental retardation*

	Observed frequency (%)	Expected frequency (%)
>+ S D	7 5	2 3
≤+2 S D >+1 S D	16 7	13 6
≤+1 S D >−1 S D	57 5	68 3
≤−1 S D >−2 S D	15 0	13 6
≤−2 S D	8 3	2 3

Present series 1977	Sweden	Unselected	<50	0–16 years	30

weight ≤2 500 g (LBW) compared to 4 3% in the average population and 39% in an unselected series of cerebral palsy (CP) children (10) during the same period There was none with a birth weight of 1 500 or less The difference in the proportion of LBW was highly significant ($p \leq 0\ 001$) in comparison with the normal as well as with the CP population No change through the years was observed

When grouping according to pathogenetic factors the mean birth weights were as shown in Table 3 It appears that the reduction of the mean birth weight was mainly referred to the children with a history of foetal deprivation of supply (7 11) with or without simultaneous histories of asphyxia/cerebral haemorrhage Children with CP as additional handicap to their severe MR consistently had a lowered mean birth weight Pathogenetically they *mainly represented one or both of the two* particular groups mentioned With the exception of Down s syndrome children with prenatal stigmata and a genetic or an untraceable aetiology had on an average normal birth weights The group with defined postnatal infections included one baby with a birth weight of 1 590 g appropriate for gestational age and in its second week of life a listeria meningitis followed by a severe hydrocephalic state The three other children in this group had birth weights of 2 620 2 760 3 780 g respectively

Gestational age

For 120/122 patients information on gestational age was obtained from obstetric records Thirty two out of 120 (27%) had been born at or before 37 completed weeks of gestation Fifteen out of 120 (12 5%) were born at or after 42 completed weeks Excluding the 39 children with Down s syndrmoe the figures were 21 and 15% respectively Compared to the general Swedish Birth Data Information Bank where the corresponding figures are 10 and 16% respectively the children with severe MR had a significantly ($p \leq 0\ 0001$) lowered gestational age

Birth weight in relation to gestational length

When comparing birth weights in relation to gestational ages according to the Swedish normal growth curve (6) the birth weights were not normally distributed There were too *many large and too many small for gestational* age (Table 4) the statistical calculations showing highly significant deviations ($p < 0\ 001$)

Associated CNS handicaps

Epilepsy (defined as recurrent epileptic seizures excluding convulsions during the first month of life and febrile convulsions under 5 years of age) was the most frequent associated CNS handicap and had occurred in 36/122 (30%) cases Twenty two *of 122 (18%) had* cerebral palsy in addition to their severe MR All syndromes of cerebral palsy were represented spastic/ataxic diplegia (9 cases) and dyskinetic syndromes (6 cases) most frequent

ly Ten of 122 (8%) of the children had epilepsy as well as cerebral palsy Severe hearing impairment was present in 4 cases and severe impairment of vision in 12 cases Seven children were hydrocephalic None had a concomitant spina bifida cystica Many of the patients had more than one of the above handicaps In total 51/122 (42%) had one or more additional CNS handicaps besides their severe MR

DISCUSSION

Most epidemiologic studies on severe MR have been restricted to prevalence data mainly employing the census method This has been well documented in the review of Abramowics & Richardson (1) who surveyed 27 community studies of severe MR from different parts of the world Very few researchers have coped with the incidence of severe MR McDonald s survey from Canada (17) in fact being the only one in recent years Compared with that study which gave an incidence of 4 6‰ for children alive at one year of age and born in 1958 in Quebec our investigation showed a lower incidence figure i e 3 3‰ Our estimated prevalence of 2 8‰ at 11–16 years was also lower than other age selected prevalence surveys An extremely thoroughly performed Swedish investigation with its census date in 1969 (19) revealed a prevalence of 4 6‰ at 10–19 years The number of cases in that series however is too small to make any statistical comparison with our result It is possible that the general high social welfare as well as the centralized and intensive perinatal care in Sweden during the last two decades might explain at least partly the lower incidence of severe MR compared with the majority of figures from other countries As will be demonstrated in part II of this study (8) we had only a few postnatal CNS infections and no case of hyperbilirubinaemia as the believed cause of severe MR together constituting only 3% of this series The corresponding estimated figure in McDonald s survey of children born in 1958 (17) was 11% indicating that in Sweden these two brain damaging factors among others had been minimized as causes of severe MR already before 1959 The higher prevalence figures in the ages 11–16 years well known from earlier series (1) are not merely due to differences in case finding procedures but also to a true cumulative increase of the incidence of severe MR (according to IQ definitions) through the years of growth As our series is considered to be complete the higher incidence figure during 1959–64 compared with the period 1965–70 is thought to be due to the latter explanation

The infant death rate (death during the first year of life) in Sweden has decreased progressively from 16 8‰ in 1959 to 11 0‰ in 1970 Furthermore perinatal gains in the form of fewer cerebral palsied children have been demonstrated (10) for the same period As will be shown in part II of this study (8) the pathogenetic factors were prenatal in 73% of the cases and perinatal in 10% The incidence of severe MR in the children born during the periods 1959–64 and 1965–70 was unchanged These data suggest that nowadays in Sweden cases of severe MR are only to a minor extent recruited from groups predominantly burdened with obvious perinatal and neonatal pathogenetic factors and that the decreasing infant mortality has not resulted in a higher incidence of severely mentally retarded children as some sceptics have feared

Our series of severe MR like some others (2 4) showed an increase in the proportion of pregnancies terminating at or before 37 completed weeks of gestation and resulting in LBW infants Åkesson (21) showed in 1966 a normal mean gestational length but more cases of unusually short as well as of unusually long gestations than expected His series however was limited to institutionalized cases and excluded all children with Down s syndrome and all those who had died before the census day Excluding the Down s syndrome children in our series the mean gestational age tended to

be normalized but was still significantly decreased ($p \leq 0.001$).

The association of very low birth weight with severe MR and cerebral palsy in earlier years has been well established (16). However among our LBW children there were no uncomplicated cases, appropriate for gestational age, and none weighing less than 1 500 g, indicating that with appropriate neonatal care routines the uncomplicated LBW infants were not at increased risk of acquiring severe MR. On the other hand, babies weighing more or less than 1 SD in relation to their gestational age were overrepresented in our series, i.e. the risk of acquiring severe MR is increased in those groups.

In the cerebral palsy study (11), the birth weights in relation to gestational ages were depressed with maintained variance, whereas in this study they diverged equilaterally, resulting both in more small for date and large for date babies.

The magnitude and importance of multihandicaps in severe MR are clearly demonstrated by our study, where 42% of the mentally retarded children had one or more CNS disabilities. This is in agreement with some other recent studies (14, 20). The most frequent problems in our series were connected with epilepsies, many of which were of a severe type, resistant to antiepileptic drugs and inviting to CNS-depressing multipharmacy. Our total figure of 30% is well in agreement with other reports (Table 5). The frequency of cerebral palsy has decreased during the period in question, also in MR children (10). In the present series, however, limited to severe MR, no decrease was found. 10 CP children were born in 1959–64 and 12 in 1965–70. CP was more than 100 times and epilepsy more than 30 times more frequent among the severely mentally retarded children than in the average Swedish population of the same ages. These high figures constitute an apparent illustration of the large body of neuropaediatric problems within the group of severely mentally retarded children.

be normalized but was still significantly decreased ($p \leq 0\ 001$)

The association of very low birth weight with severe MR and cerebral palsy in earlier years has been well established (16) However among our LBW children there were no uncomplicated cases appropriate for gestational age, and none weighing less than 1 500 g indicating that with appropriate neonatal care routines the uncomplicated LBW infants were not at increased risk of acquiring severe MR On the other hand babies weighing more or less than 1 SD in relation to their gestational age were overrepresented in our series i e the risk of acquiring severe MR is increased in those groups

In the cerebral palsy study (11) the birth weights in relation to gestational ages were depressed with maintained variance whereas in this study they diverged equilaterally resulting both in more small for date and large for date babies

The magnitude and importance of multihandicaps in severe MR are clearly demonstrated by our study where 42% of the mentally retarded children had one or more CNS disabilities This is in agreement with some other recent studies (14 20) The most frequent problems in our series were connected with epilepsies many of which were of a severe type resistant to antiepileptic drugs and inviting to CNS-depressing multipharmacy Our total figure of 30% is well in agreement with other reports (Table 5) The frequency of cerebral palsy has decreased during the period in question also in MR children (10) In the present series however limited to severe MR no decrease was found 10 CP children were born in 1959–64 and 12 in 1965–70 CP was more than 100 times and epilepsy more than 30 times more frequent among the severely mentally retarded children than in the average Swedish population of the same ages These high figures constitute an apparent illustration of the large body of neuropaediatric problems within the group of severely mentally retarded children

CASE REPORT

INFANTILE POLYARTERITIS AND KAWASAKI DISEASE

A D SMITH

From the Department of Paediatrics Raigmore Hospital Inverness Scotland

ABSTRACT Smith A D (Department of Paediatrics Raigmore Hospital Inverness Scotland) Infantile Polyarteritis and Kawasaki Disease Acta Paediatr Scand 66 381 1977.—Polyarteritis in infancy is very rare difficult to diagnose and invariably fatal A 6-month-old girl who presented with a prolonged unexplained fever and was subsequently demonstrated at post mortem examination to have polyarteritis is described The combination of polyarteritis with some unusual presenting features suggests that the case described is one of the Mucocutaneous Lymph Node Syndrome (M L.N.S) or Kawasaki Disease Polyarteritis and Kawasaki Disease are discussed with reference to the case described

KEY WORDS Infantile polyarteritis Kawasaki Disease

Polyarteritis is uncommon in childhood is extremely rare in infancy and in the infant it presents as a unique form of this connective tissue disorder A number of cases have been reported from various countries in the last ten years (2 8 10) A further case in which the histopathological diagnosis of polyarteritis was made at post mortem examination is described and the implications of the findings are discussed

CASE REPORT

A 6-month-old girl became unwell 2 weeks before admission and was treated by her family doctor for otitis media and oral thrush with ampicillin and nystatin for 7 days The girl appeared to improve but her condition subsequently deteriorated and she was admitted to hospital with a fever vomiting and loose green stools neck stiffness and a rash The mother had also noticed a large gland in the infant s neck

On examination she was irritable cried constantly and held her neck retracted She had an erythematous rash on the trunk a large left cervical lymph node a left subconjunctival haemorrhage marked neck stiffness and a temperature of 40 2 C There was no evidence of oral thrush but the lips were dry and there was intense redness of both the lips and buccal mucosa The liver was enlarged and firm but there was no splenomegaly

The only abnormal results of the investigations on admission were a haemoglobin 9 9 g/dl white cell count 22 000×10⁹/l with 42% polymorphs 30% lymphocytes 2% eosinophils 8% monocytes 16% stab cells and 2% myelocytes a bilirubin of 40 micromol/l S G O T 175 I U S G P T 143 I U and alkaline phosphatase 171 I U Other investigations with normal results included microscopy and culture of cerebrospinal fluid blood and urine stool cultures and chest X ray The E S R was 28 mm in the first hour

She was treated with chloramphenicol penicillin and sulphadiazine in the expectation that the illness was due to a bacterial infection She remained ill with remittent fever and although her rash disappeared the neck stiffness persisted and the white cell count remained elevated above 25 000×10 /l She developed a moderate degree of abdominal distension and grunting respiration The liver function tests returned to normal with the bilirubin 9 micromol/l S G O T 46 I U S G P T 34 I U other investigations included IgG 12 00 g/l IgA 1 6 g/l IgM 0 88 g/l alpha foetoprotein and hepatitis B antigen not detected intravenous pyelogram and radiological and ultrasonic screening for an intra abdominal abscess normal and electron microscopy and tissue cultures for viruses were negative The Widal reaction and complement fixation titres to viruses and other agents including herpes simplex toxoplasma cytomegalovirus rubella and rickettsia were all less than 1 4

After 12 days the therapy was changed to gentamicin without improvement in her condition The erythematous

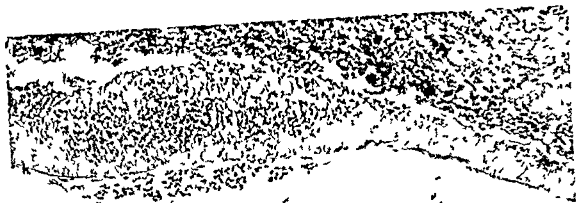

Fig 1 Major coronary artery—high power micrograph showing focus of arteritis with destruction of the elastic lamina and stenosis

Fig 2 Myocardium—half of the field shows a considerable loss of muscle cells and a heavy infiltrate of chronic inflammatory cells

rash reappeared and became florid and widespread She became severely pyrexial and died suddenly 17 days after admission

Post mortem results

The gross findings at post mortem examination consisted of a randomly distributed skin rash minor subarachnoid haemorrhage around the vertex and a smaller than normal thymus

The major microscopic abnormalities were present in the heart The main coronary arteries were affected by multifocal transmural destructive arteritis with severe luminal stenosis (Fig 1) There was multifocal necrosis of myocardium and most of the non necrotic tissue showed an active non specific myocarditis (Fig 2) Isolated examples of previous arteritic episodes were found in one lung and in relation to one lymph node The liver showed active non specific inflammation of many portal tracts This was associated with minor architectural disorganisation of the related limiting plates of lobule cells There was profound atrophy of the thymic cortex

Specimens of all tissues were processed for micro organismal culture (protozoa bacteria and viruses) with negative results The results of other post mortem investigations were antinuclear factor autoimmune fluorescence antibody tests and R A latex globulin test all negative serum IgE not detected and serum complement C_3 1 6 g/l

DISCUSSION

The term periarteritis nodosa was used in 1866 by Kussmaul and Maier to describe an inflammatory disease of medium and small arteries The more accurate term polyarteritis is now used The disease in adults is characterised by its diverse clinical manifestations and multi system involvement Classical infantile poly arteritis nodosa (I P N) is a diagnosis usually made only at post mortem examination but the clinical features and pathological findings distinguish this disease from that found in older children and adults

The sex incidence is equal and despite the variability of clinical manifestations a review of reported cases (8) suggested that a pattern of clinical features existed Later reports support this view (2 10) The features are a prolonged fever unresponsive to antibiotic therapy an erythematous rash an upper respiratory tract infection with conjunctivitis and a persistent leukocytosis in the absence of infection These authors suggest that these features in association with urinary protein or cells cardiomegaly or changes indicating left ventricular hypertrophy or ischaemia on the E C G should alert the clinician to the diagnosis of I P N Other findings include diarrhoea peripheral oedema neck stiffness convulsions and hemiplegia The diagnosis however remains difficult and is not usually clarified by biopsies The disease is usually fatal and death may be sudden and unexpected often at an early stage in the illness

Pathological changes are usually restricted to the major coronary arteries which are invariably and severely affected by polyarteritis Aneurysmal dilatation is often present and has been demonstrated during the illness by cardiac cine angiography (1) Death results from coronary thrombosis or rupture of an aneurysm

The case described demonstrates many of the features of classical I P N However three prominent clinical signs of this case are not usually described in I P N and require further consideration These are the cervical lymph adenopathy the intense redness of the lips and buccal mucosa and the conjunctival haemorrhage

In 1974 Kawasaki et al (5) reviewed an acute febrile disease which Kawasaki had originally described in 1967 in Japan (4) and which affected infants and young children The main features are prolonged fever a polymorphous rash redness of the lips tongue and mouth conjunctival congestion redness and oedema of the extremeties with membranous desquamation of the fingertips in the convalescent stage and acute swelling of the cervical lymph nodes They called this the Mucocutaneous Lymph Node Syndrome (M L N S) and it has now been designated Kawasaki Disease (K D) Other features include cardiac failure diarrhoea urinary protein or cells leukocytosis mild anaemia an increased E S R aseptic meningitis and raised serum transaminases The incidence which seems to be increasing is highest in the first year of life and greater in males than in females (1 5 1) All the original cases (4) recovered

Fig 1 Major coronary artery—high power micrograph showing focus of arteritis with destruction of the elastic lamina and stenosis

Fig 2 Myocardium—half of the field shows a considerable loss of muscle cells and a heavy infiltrate of chronic inflammatory cells

rash reappeared and became florid and widespread She became severely pyrexial and died suddenly 17 days after admission

Pathological changes are usually restricted to the major coronary arteries which are invariably and severely affected by polyarteritis Aneurysmal dilatation is often present and has been demonstrated during the illness by cardiac cine angiography (1) Death results from coronary thrombosis or rupture of an aneurysm

The case described demonstrates many of the features of classical I P N However three prominent clinical signs of this case are not usually described in I P N and require further consideration These are the cervical lymph adenopathy the intense redness of the lips and buccal mucosa and the conjunctival haemorrhage

In 1974 Kawasaki et al (5) reviewed an acute febrile disease which Kawasaki had originally described in 1967 in Japan (4) and which affected infants and young children The main features are prolonged fever a polymorphous rash redness of the lips tongue and mouth conjunctival congestion redness and oedema of the extremeties with membranous desquamation of the fingertips in the convalescent stage and acute swelling of the cervical lymph nodes They called this the Muco cutaneous Lymph Node Syndrome (M L N S) and it has now been designated Kawasaki Disease (K D) Other features include cardiac failure diarrhoea urinary protein or cells leukocytosis mild anaemia an increased E S R aseptic meningitis and raised serum transaminases The incidence which seems to be increasing is highest in the first year of life and greater in males than in females (1 5 1) All the

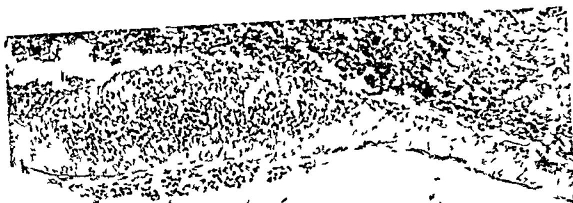

Fig 1 Major coronary artery—high power micrograph showing focus of arteritis with destruction of the elastic lamina and stenosis

Fig 2 Myocardium—half of the field shows a consider able loss of muscle cells and a heavy infiltrate of chronic inflammatory cells

but it is now apparent that 1–2% of patients, usually in early infancy die suddenly and all have histo pathological changes indistinguish able from I P N (9) Cardiac angiography (3) shows that up to 60% of the patients who re cover have abnormalities of the coronary arteries including aneurysms and stenosis

The aetiology is unknown and although a hypersensitivity mechanism is implicated in the adult form of polyarteritis, evidence of this is usually lacking in infants Raised serum IgE has, however been described in both I P N (6) and K D (7) The role of any micro organism in the pathogenesis of the disease has not yet been confirmed There is no satis factory treatment for either I P N or for the usually self limiting condition of K D

Kawasaki Disease accounts for the features of the case reported, it is submitted that mem branous desquamation of the fingertips and coronary artery aneurysms were not seen be cause of the early death of the infant The re lationship between I P N and K D is unclear at present but I P N may represent the fatal end of a disease spectrum which is more com monly manifested as the relatively benign K D If this is proved to be true then a solution to the aetiology of arterial inflammatory dis ease may be nearer The increasing incidence of K D may be the result of an environmental factor yet to be identified (7)

CASE REPORT

COMPLETE HEART BLOCK IN A YOUNG CHILD PRESUMABLY DUE TO MYCOPLASMA PNEUMONIAE MYOCARDITIS

B FRIEDLI F RENEVEY and J C ROUGE

From the Clinique Universitaire de Pediatrie Hopital Cantonal Geneva Switzerland

ABSTRACT Friedli B Renevey F and Rouge J C (Clinique Universitaire de Pediatrie Geneva Switzerland) Complete heart block in a young child presumably due to Mycoplasma Pneumoniae Myocarditis Acta Paediatr Scand 66 385 1977.—The case is described of an 18 months old boy with sudden onset complete heart block heralded by Stokes-Adams attacks General signs of viral illness preceded and accompanied the syndrome this along with angiographic evidence of a poorly contracting left ventricle led to the diagnosis of non bacterial myocarditis Serologic tests disclosed a significant rise in antibodies against mycoplasma pneumoniae (1/16 to 1/128) The His-bundle electrogram showed a block above the His-bundle but fairly widespread damage to the conduction system is suspected The complete heart block proved to be permanent and a fixed rate pacemaker had to be implanted

KEY WORDS Atrioventricular block myocarditis mycoplasma pneumoniae His-bundle electrogram pacemaker

Complete heart block (CHB) in infants and young children is usually congenital (7) it is associated with heart defects in approximately one third of the cases (6) Acquired heart block is rare in this age group A few cases of heart block usually transient have been described in association with myocarditis (2 4 10) The case reported here presented with Stokes Adams attacks at the age of 18 months and required implantation of a permanent pacemaker the heart block occurred during a viral like illness with evidence of myocarditis

CASE HISTORY

G M was first admitted to the hospital at the age of 18 months He had previously been well He was born at term and his development was normal a normal heart rate had been documented at birth and at a later medical examination

Three weeks before admission he had an upper respiratory tract infection which subsided rapidly but fever recurred 4 days prior to admission On 13 January 1975 he was admitted to hospital with a history of ? syncopal episodes occurring within the previous twelve hours These attacks were associated with brief loss of consciousness and were followed by drowsiness there were no convulsions

At the time of admission he was alert but irritable he had a temperature of 38 6 C a red throat and enlarged cervical lymph nodes The heart rate was 55/min and regular Blood pressure was 110/60 Auscultation of the heart revealed a first sound varying in intensity but no murmur There were no signs of heart failure Neurological examination was normal

The white blood count was 14 900/mm³ with 55% granulocytes 33% lymphocytes and 15% monocytes Other blood tests and CSF were normal A chest X ray revealed moderate cardiomegaly (Fig 1) The ECG showed complete atrioventricular (A V) block with a wide QRS complex of right bundle branch block (RBBB) configuration (Fig ?) The T waves were very wide ($QT=$ 0 64 sec) deep and inverted

He was treated initially with i v Atropine and Isoproterenol with little effect The heart rate remained between 40 and 60/min and signs of heart failure appeared The ECG remained unchanged apart from disappearance of the T wave abnormalities

On the day following admission right and left heart

but it is now apparent that 1–2% of patients usually in early infancy, die suddenly and all have histo pathological changes indistinguish able from I P N (9) Cardiac angiography (3) shows that up to 60% of the patients who re cover have abnormalities of the coronary arteries, including aneurysms and stenosis

The aetiology is unknown and although a hypersensitivity mechanism is implicated in the adult form of polyarteritis, evidence of this is usually lacking in infants Raised serum IgE has however, been described in both I P N (6) and K D (7) The role of any micro organism in the pathogenesis of the disease has not yet been confirmed There is no satis factory treatment for either I P N or for the usually self limiting condition of K D

Kawasaki Disease accounts for the features of the case reported it is submitted that mem branous desquamation of the fingertips and coronary artery aneurysms were not seen be cause of the early death of the infant The re lationship between I P N and K D is unclear at present but I P N may represent the fatal end of a disease spectrum which is more com monly manifested as the relatively benign K D If this is proved to be true then a solution to the aetiology of arterial inflammatory dis ease may be nearer The increasing incidence of K D may be the result of an environmental factor yet to be identified (7)

but it is now apparent that 1–2% of patients usually in early infancy die suddenly and all have histo pathological changes *indistinguish* able from I P N (9) Cardiac angiography (3) shows that up to 60% of the patients who re cover have abnormalities of the coronary arteries including aneurysms and stenosis

The aetiology is unknown and although a hypersensitivity mechanism is implicated in the adult form of polyarteritis evidence of this is usually lacking in infants Raised serum IgE has however, been described in both I P N (6) and K D (7) The role of any micro *organism in the pathogenesis of the disease* has not yet been confirmed There is no satis factory treatment for either I P N or for the usually self limiting condition of K D

Kawasaki Disease accounts for the features of the case reported it is submitted that mem branous desquamation of the fingertips and coronary artery aneurysms were not seen be cause of the early death of the infant The re lationship between I P N and K D is unclear at present but I P N may represent the fatal end of a disease spectrum which is more com monly manifested as the relatively benign K D If this is proved to be true then a solution to the aetiology of arterial inflammatory dis ease may be nearer The increasing incidence of K D may be the result of an environmental factor yet to be identified (7)

CASE REPORT

COMPLETE HEART BLOCK IN A YOUNG CHILD PRESUMABLY DUE TO MYCOPLASMA PNEUMONIAE MYOCARDITIS

B FRIEDLI F RENEVEY and J C ROUGE

From the Clinique Universitaire de Pediatrie Hopital Cantonal Geneva Switzerland

ABSTRACT Friedli B Renevey F and Rouge J C (Clinique Universitaire de Pediatrie Geneva Switzerland) Complete heart block in a young child presumably due to Mycoplasma Pneumoniae Myocarditis Acta Paediatr Scand 66 385 1977.—The case is described of an 18 months old boy with sudden onset complete heart block heralded by Stokes-Adams attacks General signs of viral illness preceded and accompanied the syndrome this along with angiographic evidence of a poorly contracting left ventricle led to the diagnosis of non bacterial myocarditis Serologic tests disclosed a significant rise in antibodies against mycoplasma pneumoniae (1/16 to 1/128) The His-bundle electrogram showed a block above the His bundle but fairly widespread damage to the conduction system is suspected The complete heart block proved to be permanent and a fixed rate pacemaker had to be implanted

KEY WORDS Atrioventricular block myocarditis mycoplasma pneumoniae His-bundle electrogram pacemaker

Complete heart block (CHB) in infants and young children is usually congenital (7) it is associated with heart defects in approximately one third of the cases (6) Acquired heart block is rare in this age group A few cases of heart block usually transient have been described in association with myocarditis (2 4 10) The case reported here presented with Stokes Adams attacks at the age of 18 months and required implantation of a permanent pacemaker the heart block occurred during a viral like illness with evidence of myocarditis

CASE HISTORY

G M was first admitted to the hospital at the age of 18 months He had previously been well He was born at term and his development was normal a normal heart rate had been documented at birth and at a later medical examination

Three weeks before admission he had an upper respiratory tract infection which subsided rapidly but fever recurred 4 days prior to admission On 13 January 1975 he was admitted to hospital with a history of 2 syncopal episodes occurring within the previous twelve hours These attacks were associated with brief loss of consciousness and were followed by drowsiness there were no convulsions

At the time of admission he was alert but irritable he had a temperature of 38 6 C a red throat and enlarged cervical lymph nodes The heart rate was 55/min and regular Blood pressure was 110/60 Auscultation of the heart revealed a first sound varying in intensity but no murmur There were no signs of heart failure Neurological examination was normal

The white blood count was 14 900/mm with 55% granulocytes 33% lymphocytes and 15% monocytes Other blood tests and CSF were normal A chest X ray revealed moderate cardiomegaly (Fig 1) The ECG showed complete atrioventricular (A V) block with a wide QRS complex of right bundle branch block (RBBB) configuration (Fig 2) The T waves were very wide (QT= 0 64 sec) deep and inverted

He was treated initially with i v Atropine and Isoproterenol with little effect The heart rate remained between 40 and 60/min and signs of heart failure appeared The ECG remained unchanged apart from disappearance of the T wave abnormalities

On the day following admission right and left heart

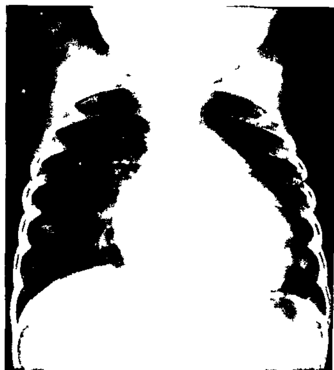

Fig 1 Chest X ray on the day of admission showing *cardiomegaly and slight pulmonary venous congestion*

catheterization was performed including a His bundle electrogram The hemodynamic data were normal apart from an increased left ventricular end-diastolic pressure (12 mmHg) A left ventricular angiogram showed enlargement of the cavity and poor left ventricular contractility The His bundle potential was found with some difficulty it was recorded as a rather slow deflection preceding every V wave thus locating the CHB above the His bundle (Fig 3) The H–V interval was 25 msec which is *within normal limits for this age group (1) A transvenous* pacing electrode was left in the right ventricle and the child was digitalized Sixteen days after the initial Stokes Adams attacks there was no sign of return to sinus rhythm and a permanent epicardial pacemaker at a fixed rate of 95/min was implanted

Among a variety of complement fixation tests done (Table 1) the titre of antibodies against mycoplasma

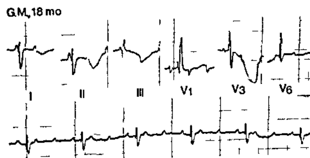

Fig 2 ECG on admission showing complete heart block a wide QRS complex with *RBBB pattern* and T wave abnormalities

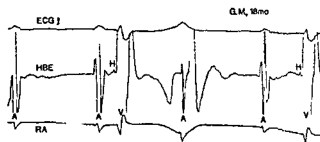

Fig 3 His bundle electrogram The upper trace is a surface ECG lead I (ECG I) in the middle is the His bundle electrogram (HBE) the lower trace is a recording from the right atrium (RA) Note rather sluggish H-deflection preceding the V waves

pneumoniae rose significantly from 1/16 on the day of admission to 1/128 ten days later A high titre of antibodies against Respiratory Syncitial Virus on admission fell subsequently *probably indicating infection with this agent* prior to the myocarditis in relation with the upper respiratory infection three weeks before admission Cold agglutinins were looked for late in the course of the illness and were not found

The child left hospital a week following implantation of the pacemaker and has since been asymptomatic Digoxin was discontinued after one month

At follow up 20 months after the Stokes Adams attack the child is very well requires no medication and is de*veloping normally There has been no sign of return to* normal sinus rhythm

COMMENT

CHB in infants and young children is usually of congenital origin Death from congestive heart failure may occur in this condition during early infancy most patients surviving to the second year of life are likely to be asymptomatic throughout childhood Stokes Adams attacks occurring in a small percentage only

Table 1 *Results of complement fixation tests*

	Admission	10 days after
Q Fever	Neg	Neg
Psittacosis	Neg	Neg
Mycoplasma pneumoniae	1 16	1 128

Adenovirus	Neg	Neg
Mumps	1 8	1 8
Enterovirus	Neg	Neg

(6) In this age group acquired heart block un related to congenital heart disease is rare in the large series published by Nakamura & Nadas (7) only 4 children out of 61 with CHB fell into this category One had heart block with endocardial fibroelastosis in one the origin was unknown and in two myocar ditis was strongly suspected In the case pres ented here normal heart rates had been re corded by the pediatrician on several occa sions prior to the current illness Bradycardia was first noted following two Stokes Adams attacks There is therefore little doubt that the A–V block was acquired Considering the etio logy we believe that there is much evidence in favour of infectious non bacterial myo carditis the child had a febrile illness with upper respiratory tract infection 20 days and again 3 days before onset of the Stokes Adams attacks he was febrile on admission had a red throat and a slight leucocytosis with 15% mononuclear cells suggesting viral infection There was evidence of diffuse myocardial dis ease with a very large heart pulmonary ven ous congestion and a poorly contracting left ventricle on the cine angiogram as well as a high left ventricular end-diastolic pressure

Among the many non bacterial agents proven or suspected to cause myocarditis mycoplasma pneumoniae has been in frequently reported (3 5) In the present case this organism is suspected because of a signifi cant rise of titre of mycoplasma pneumoniae antibodies Pneumonia was not present on ad mission as it was in the case of El Khatib et al (3) however pneumonia is not a constant feature of mycoplasma pneumoniae infection it was absent in three of twenty cases collected by Lambert (5)

CHB due to viral myocarditis has been in frequently reported In one case mumps virus was strongly suspected as being the cause (4) in all others the exact etiology remained ob scure In almost all cases reported to date the outcome was benign with return to normal sinus rhythm within a few days this unfor tunately did not happen in the present case and a fixed rate permanent pacemaker had to be implanted two weeks after the initial episode of block We know only of one case of ac quired heart block requiring permanent pacing in a young child reported by Serradimigni et al (9) the etiology in that case remained un known although a viral origin was suspected

On the basis of the clinical history (presence of Stokes Adams attacks) and particularly the surface ECG we had assumed that our patient had CHB distal to the His bundle Indeed the ventricular rate was slow and the QRS com plexes wide However the His bundle electro gram revealed a block proximal to the His For the following reasons we believe that damage to the conduction system is diffuse

1) the His bundle electrogram suggests damage to the A–V nodal area (CHB above His)

2) the ECG indicates damage to the right bundle branch (complete RBBB)

3) a lesion in the junctional area and bundle of His must be suspected to explain the rather slow junctional escape rhythm which could not be accelerated by Isoproterenol or Atro pine as well as the occurrence of Stokes Adams attacks The His bundle electrogram further substanciates this hypothesis Indeed according to Puech (8) a sluggish H-deflec tion as seen in our case indicates damage within the His bundle

Interestingly right bundle branch block was found in two previously reported cases (9 2) it has persisted in the latter case after return to sinus rhythm

CASE REPORT

INFANTILE CONVULSIONS
TRANSIENT INFANTILE HYPOCALCEMIA ASSOCIATED WITH SKELETAL DEFORMITIES

J L VAN DER HORST and J F M HÖLSCHER

From the Department of Paediatrics Sint Lucas Ziekenhuis Amsterdam The Netherlands

ABSTRACT Van der Horst J L and Holscher J F M (Department of Paediatrics Sint Lucas Ziekenhuis Amsterdam The Netherlands) Infantile convulsions Transient infantile hypocalcemia associated with skeletal deformities Acta Paediatr Scand 66 389 1977.—An infant with skeletal deformities and hypocalcemic convulsions is described The convulsions which were first noted in the 5th week of life as well as the low serum calcium level were transient The skeletal deformities consisted of deformation of the terminal phalanges of the right third finger and right second toe syndactyly of the third and fourth finger of both hands and left pes equinovarus X ray examination revealed abnormal shape and structure of some bones of the hands The most likely diagnosis is transient congenital idiopathic hypoparathyroidism which has not yet been described in association with congenital skeletal anomalies

KEY WORDS Infantile hypocalcemia tetanic convulsions transient congenital idiopathic hypoparathyroidism multiple congenital skeletal anomalies

The paediatrician confronted with a convulsive infant will undoubtedly consider metabolic disorders as an etiologic factor When the calcium concentration in the blood of such an infant is sufficiently decreased the diagnosis is hypocalcemic tetany Hypocalcemic tetanic convulsions often resemble epileptic seizures especially in the neonate

Serum calcium is controlled by the parathyroid glands Moreover normal renal function—especially phosphate excretion—is necessary for maintaining calcium homeostasis Also intestinal calcium and phosphate absorption should be unimpaired (4) In tetany one of these factors is not properly functioning

CASE HISTORY

The patient Mustafa a Turkish infant was admitted to the hospital at the age of 4 days In the first trimester of pregnancy the mother tried without result to induce an abortion by jumping from a great height Otherwise pregnancy and delivery were uneventful and birth weight was in the normal range Skeletal deformities were unknown in both parental families

Ten days before admission the parents recognized a convulsion the child was cyanotic displayed seizures and foamed at the mouth On the day of admission several convulsions occurred and the child was admitted while having a convulsion This was successfully treated by intravenous diazepam Mustafa remained restless with small myoclonic jerks

Physical examination

The face was round (Fig 1) The terminal phalanges of the right third finger and the right second toe were deformed (Figs 2 and 3) There was syndactyly of the third and fourth fingers of both hands (Fig 2) The left foot was a pes equinovarus (Fig 4) while in the right leg a constricting band was visible

X rays showed absence of the terminal phalanges of the third and fourth finger of the right hand (Fig 5) a broad and curved first metacarpal bone and short broadened phalanges with abnormal bone structure

Biochemical data and clinical course

Blood glucose and blood urea were in the normal range respectively 5 2 mmol/l and 1 3 mmol/l Aspect and composition of the stools were normal

Serum calcium was low 1 6 mmol/l Serum phosphate

CASE REPORT

INFANTILE CONVULSIONS
TRANSIENT INFANTILE HYPOCALCEMIA ASSOCIATED WITH SKELETAL DEFORMITIES

J L VAN DER HORST and J F M HÖLSCHER

From the Department of Paediatrics Sint Lucas Ziekenhuis Amsterdam The Netherlands

ABSTRACT Van der Horst J L and Holscher J F M (Department of Paediatrics Sint Lucas Ziekenhuis Amsterdam The Netherlands) Infantile convulsions Transient infantile hypocalcemia associated with skeletal deformities Acta Paediatr Scand 66 389 1977.—An infant with skeletal deformities and hypocalcemic convulsions is described The convulsions which were first noted in the 5th week of life as well as the low serum calcium level were transient The skeletal deformities consisted of deformation of the terminal phalanges of the right third finger and right second toe syndactyly of the third and fourth finger of both hands and left pes equinovarus X ray examination revealed abnormal shape and structure of some bones of the hands The most likely diagnosis is transient congenital idiopathic hypoparathyroidism which has not yet been described in association with congenital skeletal anomalies

KEY WORDS Infantile hypocalcemia tetanic convulsions transient congenital idiopathic hypoparathyroidism multiple congenital skeletal anomalies

The paediatrician confronted with a convulsive infant will undoubtedly consider metabolic disorders as an etiologic factor When the calcium concentration in the blood of such an infant is sufficiently decreased the diagnosis is hypocalcemic tetany Hypocalcemic tetanic convulsions often resemble epileptic seizures especially in the neonate

Serum calcium is controlled by the parathyroid glands Moreover normal renal function—especially phosphate excretion—is necessary for maintaining calcium homeostasis Also intestinal calcium and phosphate absorption should be unimpaired (4) In tetany one of these factors is not properly functioning

CASE HISTORY

The patient Mustafa a Turkish infant was admitted to the hospital at the age of 4 days In the first trimester of pregnancy the mother tried without result to induce an abortion by jumping from a great height Otherwise pregnancy and delivery were uneventful and birth weight was in the normal range Skeletal deformities were unknown in both parental families

Ten days before admission the parents recognized a convulsion the child was cyanotic displayed seizures and foamed at the mouth On the day of admission several convulsions occurred and the child was admitted while having a convulsion This was successfully treated by intravenous diazepam Mustafa remained restless with small myoclonic jerks

Physical examination

The face was round (Fig 1) The terminal phalanges of the right third finger and the right second toe were deformed (Figs 2 and 3) There was syndactyly of the third and fourth fingers of both hands (Fig 2) The left foot was a pes equinovarus (Fig 4) while in the right leg a constricting band was visible

X rays showed absence of the terminal phalanges of the third and fourth finger of the right hand (Fig 5) a broad and curved first metacarpal bone and short broadened phalanges with abnormal bone structure

Biochemical data and clinical course

Blood glucose and blood urea were in the normal range respectively 5 2 mmol/l and 1 3 mmol/l Aspect and composition of the stools were normal

Serum calcium was low 1 6 mmol/l Serum phosphate

Fig 1 Patient Mustafa at admission

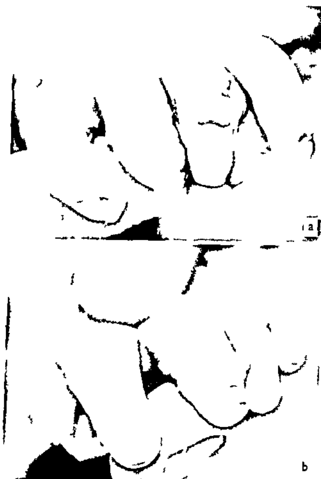

Fig 2 Right and left hand with deformity of right third finger and bilateral syndactyly of fingers

was 2 0 mmol/l and alkaline phosphatase was 1 28 nmol s⁻¹/l Serum magnesium was not determined

Daily intramuscular administration (2) of 10 20 U S P units of parathyroid extract (Parathormon Lilly) for 12 days resulted in a rise of serum calcium to 2 2 mmol/l Subsequently serum calcium fell to 1 6 mmol/l on the 8th hospital day in spite of continued administration of PTE (Fig 6) Phosphate intake was not excessive initially the child was fed on human milk and later on a mixture of human and humanized milk (Almiron M2) with a normal Ca/P ratio

With anticonvulsive therapy consisting of diazepam and phenobarbital convulsions no longer occurred but the patient remained restless and irritable for several days after admission

Administration of PTE was stopped 13 days after admission Still serum calcium rose spontaneously to a level of 2 1 mmol/l 10 days later (Fig 6) Four days later administration of PTE was resumed this time in a dosage of 60 U S P units Serum calcium continued to rise and reached a normal value (2 4 mmol/l) after another 5 days At that time serum phosphate was 1 7 mmol/l Serum calcium remained normal after cessation of PTE treatment 4 days later (Fig 6)

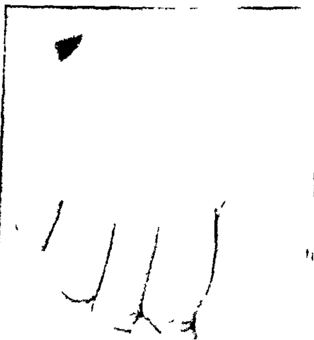

Fig 3 Right foot with deformity of second toe

DISCUSSION

The patient described had hypocalcemic tetany Renal insufficiency excessive intake

Fig 4 Pes equinovarus of left foot constricting band in right leg

Fig 5 X ray of hands absence of terminal phalanges fingers III and IV of the right hand

of phosphate and intestinal malabsorption (4) could be excluded as causes for the lowered serum calcium level

Neonatal hypocalcemia was unlikely since the first symptoms appeared in the 5th week of life *Rickets* (5) was excluded by the normal concentration of alkaline phosphatase and the absence of rachitic changes on the X ray photographs

A further possibility was *hypoparathyroidism* The *chronic* type of this disease could be ruled out since hypocalcemia did not persist

Transient hypoparathyroidism can be due to *maternal hyperparathyroidism* (6) The mother of the child did not show any signs of this condition however the serum calcium was 2 4 mmol/l phosphate 0 9 mmol/l and alkaline phosphatase 0 20 nmol s^{-1}/l

Fig 6 Biochemical data of the patient upon admission to hospital

Fig 1 Patient Mustafa at admission

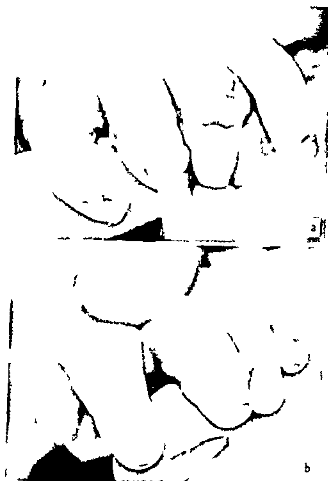

Fig 2 Right and left hand with deformity of right third finger and bilateral syndactyly of fingers

was 2 0 mmol/l and alkaline phosphatase was 1 28 nmol s^{-1}/l Serum magnesium was not determined

Daily intramuscular administration (2) of 10 20 U S P units of parathyroid extract (Parathormon Lilly) for 12 days resulted in a rise of serum calcium to 2 2 mmol/l Subsequently serum calcium fell to 1 6 mmol/l on the 8th hospital day in spite of continued administration of PTE (Fig 6) Phosphate intake was not excessive initially the child was fed on human milk and later on a mixture of *human and humanized milk (Almiron M?) with a normal* Ca/P ratio

With anticonvulsive therapy consisting of diazepam and phenobarbital convulsions no longer occurred but the patient remained restless and irritable for several days after admission

Administration of PTE was stopped 13 days after admission Still serum calcium rose spontaneously to a level of 2 1 mmol/l 10 days later (Fig 6) Four days later administration of PTE was resumed this time in a dosage of 60 U S P units Serum calcium continued to rise and reached a normal value (2 4 mmol/l) after another 5 days At that time serum phosphate was 1 7 mmol/l Serum calcium remained normal after cessation of PTE *treatment 4 days later (Fig 6)*

DISCUSSION

The patient described had hypocalcemic tetany Renal insufficiency excessive intake

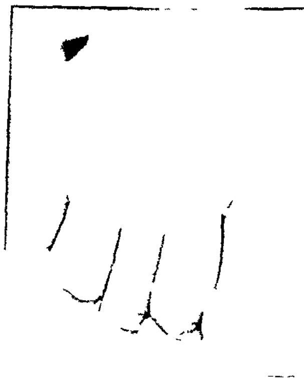

Fig 3 Right foot with deformity of second toe

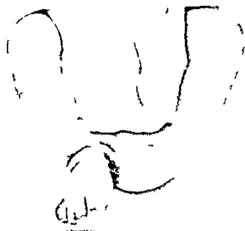

Fig 4 Pes equinovarus of left foot constricting band in right leg

Fig 5 X ray of hands absence of terminal phalanges fingers III and IV of the right hand

of phosphate and intestinal malabsorption (4) could be excluded as causes for the lowered serum calcium level

Neonatal hypocalcemia was unlikely since the first symptoms appeared in the 5th week of life *Rickets* (5) was excluded by the normal concentration of alkaline phosphatase and the absence of rachitic changes on the X ray photographs

A further possibility was *hypoparathyroidism* The *chronic* type of this disease could be ruled out since hypocalcemia did not persist

Transient hypoparathyroidism can be due to *maternal hyperparathyroidism* (6) The mother of the child did not show any signs of this condition however the serum calcium was 2 4 mmol/l phosphate 0 9 mmol/l and alkaline phosphatase 0 20 nmol s^{-1}/l

Fig 6 Biochemical data of the patient upon admission to hospital

Finally temporary hypocalcemia is seen in *transient congenital idiopathic hypoparathyroidism* described by Fanconi & Prader (3) and also by Balsan & Alizon (1) It has been suggested (3) that the cause of this condition is a primary congenital hypoplasia or dysplasia of the parathyroid glands which will become hyperplastic to correct the hypocalcemia The infants described by these authors became hypocalcemic in the first weeks of life as our patient

The positive response of serum calcium to administration of PTE was regarded by Fanconi & Prader as proof of the presence of hypoparathyroidism In our case the dose of PTE administered was much lower however and therefore the diagnosis was not definitely established Still the symptoms clinical course and spontaneous recovery are in agreement with transient congenital idiopathic hypoparathyroidism

The further course of Mustafa s illness was favourable convulsions did not occur any more Just as in the patients of Fanconi & Prader the serum calcium level remained normal When this paper was written Mustafa was 34 months old Psychomotor development as well as growth in stature had been satisfactory

To conclude although not proved Mustafa s illness should be diagnosed in our opinion as transient congenital idiopathic hypoparathyroidism The association fo this condition with multiple congenital skeletal anomalies has not been reported before

ACKNOWLEDGEMENT

We wish to thank Dr R Steendijk reader Department of Paediatrics University of Amsterdam for his valuable advice in preparing this paper

CASE REPORT

DISSEMINATED ARTHRITIS AND OSTEITIS BY CANDIDA ALBICANS IN A TWO MONTH OLD INFANT RECEIVING PARENTERAL NUTRITION

L BUSINCO G IANNACCONE D DEL PRINCIPE S LUCARELLI
E CARDI and E REZZA

From the Department of Paediatrics University of Rome Rome Italy

ABSTRACT Businco L Iannaccone G Del Principe D Lucarelli S Cardi E and Rezza E (Department of Paediatrics University of Rome Italy) Disseminated arthritis and osteitis by Candida albicans in a two month old infant receiving parenteral nutrition Acta Paediatr Scand 66 393 1977 —The case of a two-month-old female infant who after a severe diarrhoea treated with prolonged intravenous infusion in peripheral veins alternated with total parenteral feeding developed a Candida albicans septicemia (accompanied by disseminated intravascular coagulation syndrome) is reported The course of her disease was also complicated by multiple foci of osteoarthritis in both knees in the left hip and in several long bones Radiographically the foci of Candida osteitis appeared as fine erosion of the cortex and minute round areas of osteolysis in the spongiosa surrounded by a rim of perifocal sclerosis During the acute stage of Candida sepsis a transitory cellular immunodeficiency was present Treatment of Candida infection by 5 fluorocytosine was followed by complete recovery

KEY WORDS Osteoarthritis Candida albicans parenteral nutrition

Through the recently developed method of parenteral nutrition it is now possible to save infants who in the past died of starvation Nevertheless in patients so treated a conspicuous number of complications has been reported such as bacterial and mycotic sepsis thromboflebitis bone lesions hyperosmolar dehydration hypokalemia and hypocalcemia (4 6 7) Candida albicans osteoarthritis a complication previously practically unknown has been reported on three occasions in infants in the last four years (1 8 9) This is the case report of a two month old female infant who developed a sepsis due to Candida albicans with disseminated osteomyelitis during parenteral feeding and was successfully treated with 5 fluorocytosine

CASE REPORT

The patient was admitted to the hospital on December 30 1973 at 16 days of age because of high fever and severe diarrhoea Three days before her twin sister had died of a brief and violent episode of diarrhoea

She was born following normal twin pregnancy and delivery Her birth weigth was 2450 g The neonatal period was uneventful She was fed artificially with dried milk At admittance she was markedly dehydrated but on physical examination no other abnormalities were detected

Laboratory investigations gave the following results Hematocrit 73% hemoglobin 19 g/100 ml white blood cells 13 400/mm³ (4% neutrophils 6 eosinophils 2 monocytes and 50 lymphocytes) base-excess 9 mEq/l B U N 19 mg/100 ml Culture from a rectal swab yielded few colonies of *Staphylococcus aureus* and abundant growth of *Klebsiella aerogenes* Widal Wright test was negative three weeks after the admission

During the first month the diarrhoea persisted unabated Treatment consisted of infusions in peripheral veins of glucose saline solutions alternated with periods of

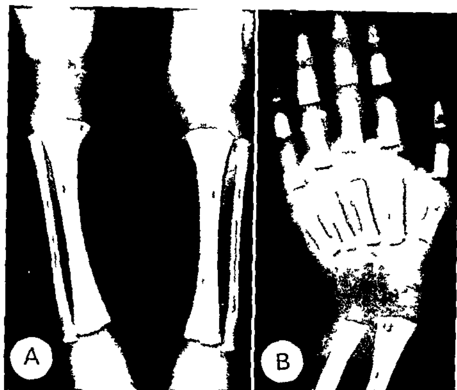

Fig 1 (A) Both knees especially the left one are swollen Small osteolytic areas are visible in the femoral and tibial metaphyses and in both anklebones (B) A rounded area of osteolysis sharply de lineated by perifocal sclerosis is evident in the distal metaphysis of the right radius

parenteral feeding with a solution containing per 100 ml (g for Aminosol and glucose mEq for the electrolytes) Aminosol 2 6 glucose 15 Na 5 K 2 Mg 1 2 Ca 1 3 P 2 Cl 6 and methicillin 100 mg Other antibiotics including gentamycin and cephalosporin were also provided

After one month of treatment with subsequent moderate improvement of the child general conditions and diarrhoea a sudden onset of large ecchymotic areas shock coma and generalised clonic seizures occurred The presence of thrombocytopenia prolonged prothrombin time and PTT along with a highly positive protamine sulphate test accompanied by deficiency of factor II V VII VIII IX led to a diagnosis of disseminated intravascular coagulation syndrome Treatment was given *for five days (heparin 200 U/kg every 4 hours hydrocorti*sone 25 mg/kg every 8 hours) After 13 days while the ecchymotic areas were disappearing a new set of complications took place fever and oral thrush appeared and Candida albicans was found in blood culture In the following days the knees became swollen and painful the left thigh being kept in a flexed position The ankles and the shoulder joints were subsequently involved On radiological examination there were signs of articular effusion in both knees with widening of the articular spaces and capsular distension The metaphyses of several long bones and of the tarsal bones showed fine erosions of the cortex and several minute areas of osteolysis in the spongiosa round shaped and sharply delineated by perifocal sclerosis (Fig 1) Similar lesions were present in the nuclei of both anklebones Neither lesions of the diaphyses nor periosteal reaction were observed

Candida albicans was isolated repeatedly from the whitish purulent material obtained by arthrocentesis of both knees and from blood cultures

Treatment with 5 fluorocytosine (Ancotil®) was immediately begun 100 mg/kg were administered daily intravenously in three divided doses After 22 days of i v treatment which was well tolerated the drug was administered by mouth at the same daily dose for a further period of 6 weeks Cultures from knee exudates and blood were negative after 13 and 20 days respectively Osteoarthritis of the left hip produced a dislocation of the femural head which was treated by means of traction on the lower limb and surgical reduction

The patient was discharged at five months of age in good health At a follow up 14 months later there was complete disappearance of the bone lesions

METHODS

Immunological tests were performed as described in our previous papers (5 10)

System B evaluation

Serum immunoglobulins levels were IgG 730 IgM 25 IgA 31 mg/100 ml during the acute stage of infection following recovery and at later follow up all values were increased Anti A and anti B isohaemoagglutinins were present

Three doses of typhoid parathyphoid vaccine caused a normal antibody response The Candida agglutinins were 1 40 during the acute stage and absent after 4 months The number of peripheral lymphocytes with membrane immunoglobulins and of those with receptors for C_3 (B lymphocytes) were normal

System T evaluation (Table I)

Delayed skin test sensitivity to Candida (Dermatophytin 1 10 Hollister Stier) PPD (10 UT Sclavo) PHA (μg 2 Wellcome) and DNCB were all negative initially but during convalescence Candida and DNCB responses became

Table 1 *Immunological evaluation during Candida septicemia and after the recovery*
Normal values in parentheses

	During Candida septicemia	After recovery 70 days	200 days
Candida antibodies (<1 14)	1 40	1 20	0
Delayed skin test			
Candida	Neg	+++	+++
PHA PPD SK	Neg	Neg	Neg
DNCB	Neg	Neg	+++
Rosettes forming lymphocytes (61±5)	2?	67	65
Response of lymphocytes to PHA stimulation index (>10)	9	34	30
In vitro lymphocyte response to Candida stimulation index (>10)	?	10	14

positive The proportion of circulating T lymphocytes evaluated by E rosette test was diminished In vitro responses of lymphocytes to PHA and to Candida were weak during the acute stage of Candida sepsis but became normal at recovery

The nitro-blue tetrazolium reduction of neutrophils was normal

DISCUSSION

Recently sepsis by Candida albicans has been reported in patients treated by prolonged parenteral nutrition by means of a central venous catheter (2 4 6) In our patient repeated intravenous infusions into peripheral veins were administered for prolonged periods but other factors favouring Candida infection were also present diarrhoea undernutrition treatment with antibiotics and corticosteroids Some of these factors are probably responsible for the transitory cellular immunodeficiency observed during the acute phase of the disease Moreover it has been suggested (6) that the hypertonic solution of glucose commonly used may predispose to Candida infection and it has been recently observed in man that hyperglycemia depresses the phagocytic properties of neutrophils (3)

Multiple foci of osteolysis were elicited in this infant X ray findings revealed the presence of small areas of radiolucency in the cortex at the metaphyseal level surrounded by a slight sclerotic reaction This peculiar radiological picture appears to be the hallmark of Candida osteomyelitis as it also was described in the few cases reported up to now (1 8 9) The localisation in the tarsal bones observed in our patient has never been reported

The effectiveness of 5 fluorocytosine was confirmed and also noteworthy appears the good tolerability of the drug which was administered for 9 weeks

CASE REPORT

TRISOMY 8 SYNDROME

A H BERNSEN K RASMUSSEN and J NIELSEN

From the Institute of Psychiatric Demography and Cytogenetic Laboratory Psychiatric Hospital Risskov Denmark

ABSTRACT Bernsen A H Rasmussen K and Nielsen J (Institute of Psychiatric Demography and Cytogenetic Laboratory Psychiatric Hospital Risskov Denmark) Trisomy 8 Syndrome Acta Paediatr Scand 66 397 1977.—A case report of trisomy 8 in a 17 year-old mentally retarded female is presented and the previously reported cases of trisomy 8 are reviewed in an attempt to establish the clinical characteristics of the trisomy 8 syndrome

KEY WORDS Autosomal chromosome aberration trisomy 8 mental retardation

Before 1970 there was no possibility of distinguishing between the chromosomes in group C but since 1970 (5) a number of different banding techniques have made it possible to identify each chromosome The importance of this is evident in genetic counselling in order to prevent mental retardation due to chromosome abnormalities One of the mental retardation syndromes is trisomy 8 first described in 1971 by de Grouchy et al (13) The present report deals with a case of trisomy 8 identified by chromosome examination as part of an epidemiological survey on severely mentally retarded children in the community of Århus Denmark (3) and it includes a review of previously presented cases of trisomy 8

CASE HISTORY

The patient (B S) is a 17 year old female the second child of parents who were both ?9 years old when she was born There is no consanguinity and the mother has had no miscarriages or stillbirths In the third month of the mother s pregnancy the 4 year older sister had rubella but the mother was unaffected During the whole pregnancy the mother was treated with 5 mg del ortin daily on account of allergic rhinitis and had X ray examinations of thorax and nasal sinuses Full term delivery at home without complications or signs of asfyxia birthweight 3 000 g length 51 cm She was breastfed till the age of 5 months At ten months old she was referred to hospital for suspected meningitis which however was not confirmed examination showed that the was not able to sit without support and had sideropenic anemia Hb was 5 7 mmol/l X rays of the lungs heart cranium and lower extremities were normal

At the age of 18 months she was referred to the paediatric department and adenoid vegetations were removed as she had had several attacks of catarrhal fever and otitis media The mother stated that she could sit alone 12 months old and walk at 17 months At the examination she behaved like a 6 month old child smiled fixated and grasped things with both hands sat without support but was unable to walk or stand unsupported She did not play only uttered some unintelligible sounds and showed no interest in other persons Facial appearance coarse features with a large mouth flat glabella and a slightly prominent forehead she was oligomimic and hypotonic The skin was in general dry and rough Extremities were long and slender with long fingers and toes the skin over the kn e and elbow joint was tense but without contractures Cardiac examination and EEG were normal WR and toxoplasmosis titers were negative No further examinations were performed to establish the etiology of the mental retardation

No exact information concerning her behaviour for the next 2–3 years is available but she seems to have been difficult to manage hyperactive destructive jealous with temper tantrums sleep-disturbances and only slow mental development

She attended a normal kindergarten from the age of 4 years which altered her behaviour so that she became

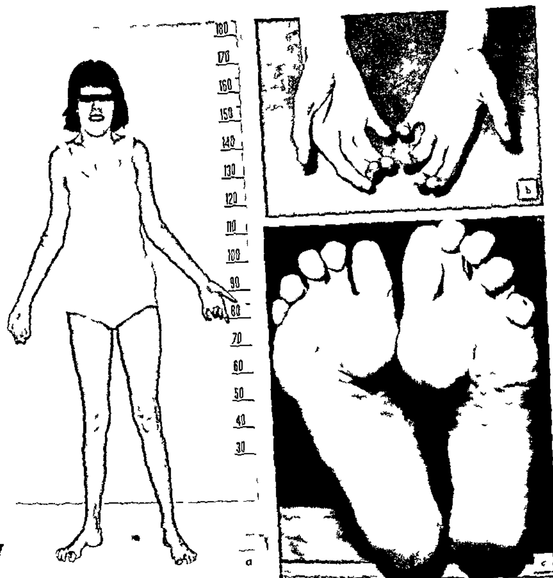

Fig 1 (*a b c*) The proband at the age of 17

19 21 25 29) and 9 cases of *partial trisomy* 8 (12 20 24 26 30)

Atkins et al (2) found it remarkable that about 30 individuals with this form of trisomy have been described in the short period from 1971 to 1974 which indicates that the condition is not extremely infrequent The incidence at birth is however unknown Only one case of C trisomy probably *trisomy 8* was found among 54 749 newborn *children* examined in USA Canada USSR Great Britain and Denmark This indicates that *the* frequency is comparatively rare probably 1 per 25 000–50 000 children

Taking into consideration that three quarters *of the* reported cases concerned partial *trisomy 8* or trisomy 8 mosaicism of varying *degree* which could account for the variations in the clinical manifestations we found it interesting to tabulate the different parameters described to each of three subtypes *full* mosaic and partial trisomy 8 (Table 1)

The picture became rather confusing *how*ever and showed no tendency towards

calmer and less destructive She was now able to walk and run with somewhat uncontrolled movements could manage eating was enuretic could say only a few simple words and understand very simple instructions

At the age of 5 6 years the speech therapist referred her to the mental retardation service but she continued in the normal kindergarten She was now clean and dry could help dressing herself and do small tasks under supervision She could talk in short sentences but the impressive language was better than the expressive

She was still somewhat aggressive and tyrannized her mother but showed more interest in both children and adults

At well over 7 years she started in the school for mentally retarded where she was difficult to manage hyperactive easily provoked by small alterations in the daily routine She had some routines of her own and tended to perseverate Her speech showed improvement but with very immature grammar and altered articulation She remained in the lower grades i e preschool classes until August 1970 when she was 12 when 3 hours of formal teaching were instituted From August 1971 she received formal teaching for 6 hours daily She is making slow progress the main difficulties being lack of concentration speech retardation and pronounced infantile behaviour

She still lives at home constant supervision is necessary in dressing and personal hygiene She cannot accept any personal responsibility and occupation is difficult she demands a great deal of attention and her sleep is restless Social development does not exceed 4 years at the age of 17 years

Psychological examinations

1964 6 5 years old) Binet Simon IQ=44
1967 (8 7 years old) Leiter IQ 55+5=60
1970 (11 8 years old) Binet Simon IQ=56 Leiter 51+5
1973 (15 0 years old) PPV test WISC CAT and Rorschach

The general impression of the first three examinations is good sense of orientation form and colour perception primitive language and indistinct pronunciation The last examination shows that she presents a slight gross motor incapacity talks a lot quite fluently but with impaired fonology she seems comfortable in the test situation but contact is superficial The cognitive tests show a mentally retarded female at the debile–imbecile level her form–colour perception facilitates simple puzzles while she fails in tests requiring reasoning

The personality tests reveal a rather harmonious girl whose main difficulty is that she cannot stop being naughty

Present state (16 years 11 months Fig 1*a b c*)
The general condition and nutritional state is good There is protruding forehead the area over the anterior fontanelle is large and hollow The hair limits are low frontally and occipitally The ears are normally differentiated and placed There is slight hypertelorism but neither strabismus nor epicanthus The nose is normal She has a large mouth with a high arched palate and protruding alveolar processes but no cleft palate and a normal tongue The neck and thorax are normal with scanty breast development (menstruation has not yet occurred) The hips are slender and axillary and pubic hair growth is normal She has long slender arms with cubitus valgus 5 extension defect in both elbows and a slight flexion defect long slender fingers with flexion contractures on the 4 ulnar fingers Mobility of the thumbs is normal The legs and feet are long slender with normal movements of the hips knees and ankles Alle toes show flexion contractures especially on the right foot The feet show cavus tendency and have hammer toes Deep skin furrows are found in the first and second interdigital spaces on the soles

Chromosome examination

Chromosome examination (Fig 2) was made on 48 hours lymphocyte cultures Q-banding and R banding were obtained with the Quinacrine–Mustard method (5) and the BUDR Acridin Orange method (10) 40 cells were analysed all of them contained 3 of the chromosome number 8 Banding patterns revealed the supernumerary chromosome number 8 to be deleted with breaking point at p 12 Thus the karyotype was 47,XX+del (8) (p 1?) Both parents and the elder sister had normal karyotypes

Dermatoglyphic investigation

The finger print pattern and the total finger ridge count (81) agree with previous findings that in trisomy 8 arches are increased in frequency and the total finger ridge count tends to be lower than that in English controls (♀126 97 ±1 82 (16))

On the palms the pattern configurations differ from those found in eleven other cases but show features typical of the syndrome On each palm there is a peripheral loop I and the pattern intensity (2 0) is above the mean value of 1 6 for normal females The pattern type I IV e t4 found on both palms of the patient is unusual in English female controls (2/900) Thenar patterns unusual ridge arrangements and higher pattern intensity than in normals are peculiarities observed in most of the patients with trisomy 8

The sole patterns show a high intensity (6 0) are unusual and were not found on either the left or on the right soles in a sample of 250 English controls (100 females+150 males) Zygodactyly occurs on both soles and on the left sole there is a whorl on area III Similar traits are observed on the soles of patients with an extra chromosome number 8 (22 23)

Examination of the blood for coagulation factor VII particularly did not reveal any deficiency of this factor (?8)

DISCUSSION

In the literature 37 cases of trisomy 8 have been reported i e 9 cases of full trisomy 8 (4 6 9 14 17 18 20 27) 19 cases of trisomy 8 mosaicism (1 2 4 6 7 8 11 13 14 15 17

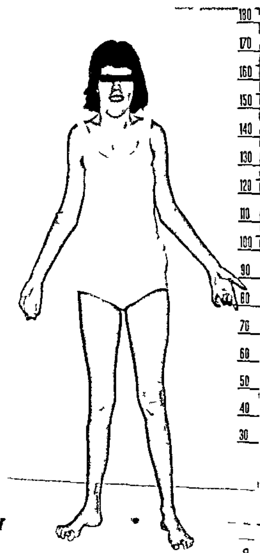

Fig 1 (*a b c*) The proband at the age of 17

19 21 25 29) and 9 cases of partial trisomy 8 (12 20 24 26 30)

Atkins *et al* (2) found it remarkable that about 30 individuals with this form of trisomy have been described in the short period from 1971 to 1974 which indicates that the condition is not extremely infrequent The incidence at birth is however unknown Only one case of C trisomy probably trisomy 8 was found among 54 749 newborn children examined in USA Canada USSR Great Britain and Denmark This indicates that the frequency is comparatively rare probably 1 per 25 000–50 000 children

Taking into consideration that three quarters of the reported cases concerned partial trisomy 8 or trisomy 8 mosaicism of varying degree which could account for the variations in the clinical manifestations we found it interesting to tabulate the different parameters described to each of three subtypes full mosaic and partial trisomy 8 (Table 1)

The picture became rather confusing however and showed no tendency towards

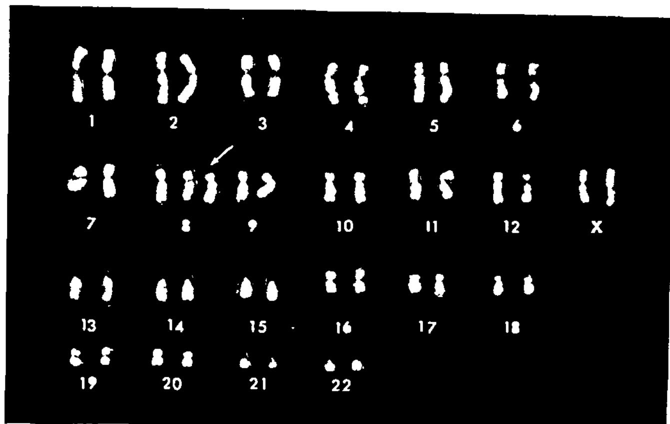

Fig 2 Karyotype 47 XX+del (8)(p 12) (BUDR Acridini Orange staining) Arrow extra chromosome no 8 with partial deletion of the short arm

clustering of signs in any single of the three subgroups There are various reasons for this some reports only summarise the most obvi *ous anomalies under headings such as* dysmorphic appearance and osseous malformations Absence of a specific sign is seldom reported No mention of a parameter tells nothing about whether the sign exists or not it might merely have been overlooked or judged as insignificant Special examinations such as X ray had not been performed in all cases especially if there were no indicative symptom and some of the signs could be a chance finding without correlation to the chromosome anomaly

Nevertheless if the frequencies of each parameter in the three subgroups are added some characteristics of the trisomy 8 syn drome emerge These are in order of de creasing frequency mental retardation seldom of severe degree deformities in the ex tremities especially of the hands and feet de formed and low set ears abnormalities in the vertebral column with spina bifida occulta or butterfly vertebrae restricted articular func *tion in all types of* joints and progressive flex ion contractures with advancing age Skull de formities may be present often with protruding forehead and a broad upturned nose with anteverted nostrils Deep skin furrows of a specific type have been found in most young children with trisomy 8 Bijlsma et al (4) con siders this sign to be age dependant thus fad ing out as the child grows older but the present case does not support this statement as the girl still has deep skin furrows in the soles at the age of 17 Similar findings were reported in a 20 year old male (8) and in a 33 year old female (27) with trisomy 8

Other typical features are the high arched palate sometimes cleft the normal or exces sive body length unusual in other autosomal chromosome trisomies In male subjects cryptorchism is often found

Table 1 *Frequency of clinical signs in various forms of trisomy 8 derived from 38 cases reported in the literature (including present case)*

Parameter	Trisomy 8		Mosaic trisomy 8	Partial trisomy 8	Combined
	B S	Incl B S			
Number described ♂/♀	1	10 (6/4)	19 (15/4)	9 (6/3)	38 (27/11)
Maternal age (?0–4? years)	?9	30 4	29 7	26 7	29 3

Gestational age (3?–40 weeks)	Full term	33–38 weeks	32–40 weeks	Full term	32–40 weeks
Birth weight (g)	3 000	3 200–4 030	2 050–4 000	2 450–3 500	2 050–4 030
Deformity of skull	×	6/10	6/19	7/9	19/38
Hypertelorism	×	5/10	4/19	2/9	11/38
Strabismus		3/10	7/19	0/9	11/38
Eye deformity		1/10	4/19	2/9	7/38
Ear deformity + low set		6/10	13/19	4/9	?3/38
Low hair limit	×	2/10	1/19	?/9	5/38
Nose deformity broad		3/10	11/19	2/9	16/38
High arched/clefted palate	×	4/10	8/19	3/9	15/38
Micro-retrognathia		4/10	6/19	2/9	1?/38
Long slender trunk/slender pelvis	×	?/10	8/19	4/9	14/38
Spinal deformity		5/10	11/19	5/9	21/38
Rib deformity		4/10	3/19	1/9	8/38
Deformities of extremities	×	9/10	15/19	?/9	31/38
Restricted articular funct	×	5/10	11/19	4/9	20/38
Skin furrows	×	5/10	11/19	1/9	17/38
Cardio-vascular defects		5/10	4/19	1/9	10/38
Urinary tract deformity		3/10	8/19	0/9	11/38
Cryptorchism		1/6	7/15	4/6	12/27
Mental retardation	×	9/10	18/19	9/9	36/38
Agenesia corp callosi			3/19		
Language impairment	×	4/10	7/19		11/38

It may be of interest also that in some cases (13 17) including the present one discrepancies are found in language development e g the impressive language is quite good compared with the expressive language and the child s general level of functioning In the reported cases a preponderance of males is found

In 1974 de Grouchy (14) suggested that a regulatory gene of coagulation factor VII synthesis is localized on chromosome 8 as he found a 50% deficiency of coagulation factor VII in three unrelated patients with trisomy 8 Neither in the present case nor in the 2 cases previously reported by Jacobsen et al (17) could deficiency of factor VII be demonstrated (28)

Observations of mental retardation combined with one or another of the above mentioned clinically easily recognized signs especially the deep skin furrows should lead to a tentative diagnosis of trisomy 8 and to chromosome examinations in order to establish the etiological diagnosis Obvious reasons for this are 1) By means of prenatal chromosome analysis the condition can be prevented in future family members if one of the parents carries a balanced translocation Such cases have been reported by Rosenthal et al (24) and Yanagisawa (30) 2) Prevention and early treatment of contractures which could otherwise be a secondary handicap problem and 3) Further in formation can con tribute to a better phenotypical limitation of the trisomy 8 syndrome

LETTERS TO THE EDITOR

Sir

In the article Erythrocyte Glucose 6 Phosphate Dehydrogenase Deficiency (G6PD Type A⁻) and Neonatal Jaundice Bienzle et al (1) express the view that G6PD deficiency is the single most important factor in the pathogenesis of severe neonatal jaundice in the West African population

We would like to bring to your notice that enzymatic deficiency of the liver might be an accessory factor contributing to the severity of the jaundice especially in those cases in which mild haemolysis results in severe hyperbilirubinemia Evidence supporting this view is the decreased salicylamide glucuronide formation (2) and decreased urinary D-glucaric acid excretion during the first week of life (3) The same decrease was observed in G6PD deficient children who developed favism after ingestion of fava beans (4 5)

The Editor has asked Dr Bienzle and co workers to comment on the letter from Dr Cassimos et al

Sir

We appreciate the point raised by Dr Cassimos and his colleagues Indeed we did not claim in our short paper (1) that neonatal jaundice in the babies we have reported *is* a *direct* consequence of low levels of glucose 6-phosphate dehydrogenase (G6PD) in their erythrocytes we have merely pointed out a strong association between the Gd^{A-} genotype and severe neonatal jaundice in Nigeria The findings in our series (described in more detail elsewhere (2) do actually indicate that in most babies there is little evidence of haemolysis (in agreement with findings from Sardinia (3) Therefore it is entirely possible that the basis for hyperbilirubinaemia lies in the liver The genes responsible for G6PD deficiency in Greece (mainly $Gd^{Mediterranean}$) and in Nigeria (Gd^{A-}) are different (4) We are not entitled to assume that the expression of Gd^{A-} and of $Gd^{Mediterranean}$ in the liver is identical However preliminary data reported in 1975 (5) soon to be published in full indicate that G6PD levels in Gd^{A-} livers are below normal Therefore we feel the suggestion made by Dr Cassimos et al is a possible working hypothesis which we have ourselves entertained it was not raised explicitly in our paper partly for the sake of brevity and partly because the

The second part of the book gives detailed information of the clinical picture and the treatment of separate types of tumours In most cases it presents didactic and informative descriptions of the nature of the tumours and brings detailed information of schemes of therapy The great experiences of the authors and the large clinical materials presented in the book will guarantee that the aspects given are conclusive and of good advice to the reader

The subject index is comprehensive and clearly edited and the illustrations and therapy schemes are very instructive Indeed this book is a stimulating practical important and generous up-to-date guide to all doctors (pediatricians surgeons radiotherapists pathologists) working in the field of pediatric oncology

Anders Kreuger

K Z Štembera K Polacek & V Šabata (eds) *Perinatal medicine* 4th European Congress of Perinatal Medicine Prague August 1974 556 pp illus Georg Thieme Publishers Stuttgart Avicenum Czechoslovak Medical Press Prague 1975 DM 98 – ISBN 3 13 5?9101-4

The editors declare that The final aim of the Proceedings is to present to the reader a survey of contemporary knowledge in the three main topics that were dealt with at the Congress This volume therefore contains the full text of the three panels dealing with Antenatal diagnosis of the at risk fetus Premature delivery and the preterm infant and The short and long term prognosis of perinatal complications In doing this the editors succeed very well Of the numerous free communications only those relating to these main themes have been included On 539 pages the reader will find a condensation product of 1974 vintage in different European centers as regards research in these major areas of perinatal medicine

A great number of illustrations tables and references as well as subject and author indexes increase the value of this volume which is clearly of great interest to all neonatologists

Olle Celander

F C Battaglia G Meschia & E J Quilligan (eds) *Perinatal medicine Review and comments* vol 1 146 pp illus The C V Mosby Company Saint Louis 1976 US$19 45

This book is a review and selection of the literature in neonatal perinatal medicine for the year 1974 It is divided in 16 chapters dealing with various aspects of perinatal medicine Pertinent papers within each field are shortly presented and commented upon by the editors with the aim to provide guidelines for an approach to this widely scattered literature for residents and postdoctoral fellows

Editor

D Fochtman & J G Raffensperger *Principles of nursing care of the pediatric surgery patient* 2nd ed Little Brown and Co Boston 1976 US$1? 50 ISBN 0-316- 8681-8

The book consists of twelve chapters dealing with the nursing care in various paediatric surgical disorders In the Foreword and Preface the role played by the nurse in diagnostics and pre and postoperative care is defined It is also stressed that the nurse has a great responsibility of her own e g to support parents of defect or handicapped children

Every chapter gives a short description of a paediatric surgical disorder In addition to the general surgical disorders the book also treats specialized paediatric surgery i e thoracic plastic and orthopaedic surgery as well as neurosurgery otological and ophthalmological surgery Each chapter is independent of the others which is an advantage for teaching purposes The pre and postoperative care in each of the conditions is presented point by point The presentation is clear and comprehensive

The pictures are of good quality and are up to date and the illustrations are clear

The need for psychological care of the whole family is repeatedly stressed especially in the chapters on burns congenital heart disease and facial malformations

Much in the book can be applied to conditions in the Scandinavian countries However from our point of view the value of the book would have been greater if it had also *included* a chapter on the cooperation between different members of the nursing staff and on how to delegate the various tasks in the nursing care Still the book should be of value in the training of nurses and on paediatric surgical wards

Kerstin Syrehn

W Schroter G Prindull & U Kaehler *Blutkrankheiten im Kindesalter* Urban & Schwarzenberg Munchen 1976 144 pp illus

This book written in German is intended as an up to-date survey of the diagnosis and treatment of haematological diseases in childhood The text is addressed to general practitioners as well as to paediatric specialists After an introductary survey of normal blood parameters including blood physiology separate chapters deal with disorders of the erythrocytes haemostasis and the leukocytes including leukemias lymphomas and reticuloendothelial diseases

With regard to the comparatively few pages of the book much information is given and most disorders and many eponymas are mentioned Especially the part concerning the erythropoietic system is clearly and thoroughly written somewhat in contrast to the other parts of the book The brief compendium style of the book necessitates more references than are now given

It is probable that doctors who are not commonly faced with paediatric haematological problems would appreciate chapters that are missing e g a survey of the rapidly expanding field of immunology of methodological problems in laboratory diagnosis and of attempts to systematize the investigations needed in different clinical situations

However the book serves as a good introduction to paediatric haematology and as a complement to textbooks in general paediatrics

Anders Kreuger

BOOK REVIEWS

Lytt I Gardner (ed) *Endocrine and genetic diseases of childhood and adolescence* W B Saunders Company Philadelphia London Toronto 1975 1403 pp 2nd ed

Six years have passed since the first edition of this text book appeared During this relatively short period there has been a rapid expansion of scientific knowledge especially in the field of genetic diseases This is *inter alia* reflected in this book by an increase in the number of pages from 1072 to 1403 Most of the chapters have been thoroughly revised and amplified The chapter on prenatal genetic diagnosis is entirely new and the contributions on psychologic aspects of genetic and endocrine diseases and on cytogenetics are greatly expanded A new classification of patients with ambiguous genitalia has been introduced It is certainly a matter of opinion how much information that should be included in a text book of this type The editor states that the purpose *of the book is to provide a definitive medical textbook* oriented to the primary care physician whether he be pediatrician internist gynecologist or family physician This has no doubt been achieved the book is in many ways excellent and can be highly recommended to the categories of readers mentioned but one may for instance ask if a detailed description how to prepare peripheral blood leukocyte cultures really ought to be included

C C Bergstrand

Moshen Ziai (ed) *Pediatrics* 1021 pp illus Little Brown & Co Boston 1975 No price given ISBN 0-316 98751-4(P)

This book is a compendium of pediatrics addressed to medical students and physicians It is a voluminous compendium of 1071 pages In the introduction the editor underlines the great diversity in growth conditions for children in developing and industrial countries He states that it is time for medical education to pay proper attention to priorities if we will get healthier children and happier nations

After this declaration one starts reading with great interest However one finds a text book of conventional type The book has become voluminous in spite of the fact that not much room has been given to deep-reaching discussions Clinical rarities are placed side by side with more common diseases which makes it difficult for a medical student to see what is really essential

In spite of the global aspects in the introduction much of the book reflects conditions in the USA Insufficient space is devoted to preventive aspects and social pediatrics The book also lacks a thorough discussion of psychological factors around the sick child and its family Nutrition is poorly dealt with Not even in the chapter on obstipation is the importance of the diet mentioned Breast feeding is not given much attention Such important fields as the battered child syndrome and sudden unexpected infant death are just touched upon

The largest part of the book is devoted to the various diseases The chapter on infectious diseases has the character of a textbook Tuberculosis has got 15 pages In contrast such an important disease as the hyaline membrane syndrome is dealt with in less than one page and all that is said about CPAP treatment is that more recently constantly maintained pulmonary inflation has saved many lives which does not give much basis for practical clinical work Allergic diseases have also been given insufficient space In the treatment of bronchial asthma one misses some modern therapeutic methods e g prophylaxis with dichromoglycate

The book ends with some appendices which treat the differential diagnosis in common clinical conditions such as unconsciousness vomiting fever seizures This chapter is perhaps the most valuable in the book In the last appendix there is a table of normal values which however is not adapted to the SI system This is true of the whole book which makes it less useful in most West European countries

Lennart Righard

H J G Bloom J Lemerle M K Neidhardt & P A Voute (eds) *Cancer in children Clinical management* 317 pp illus Springer Verlag Berlin Heidelberg New York 1975 ISBN 3 540-07261 6 US $14 20

The rapidly expanding field of pediatric oncology demands repeated survey in order to bring accumulated experience and expertise to the doctors treating childhood cancer On behalf of the Patient Care Committee of the International Union Against Cancer (UICC) 45 authors from 8 countries have collaborated and contributed to this book which due to the excellent work of the editors brings actual and thorough information on the clinical management of cancer in children

The first part of the book gives general aspects of malignant diseases as aetiology pathology and the principles and the background of different ways of treatment However a survey of the interesting recent immunological aspects on the nature of malignant diseases is lacking The book clearly emphasizes the importance of a good team work between the specialists engaged in the treatment of childhood cancer

Preparation of Manuscripts

ontributors are requested to pay particular attention the following rules governing the preparation of anuscripts *Failure to follow these rules is a frequent use of delay in the publication of articles and may sult in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate, to the ffice of the Managing Editor Professor C G Berg rand Department of Paediatrics, Malmo Allmänna ukhus S-214 01 Malmo Sweden mailed flat and ansmitted by first class mail They should be double paced typewritten on one side of the paper with wide argins Authors should exercise particular care in e preparation notation and description of figures nd tables Each table must be accompanied by a escriptive title typed above the table to which it efers A suitable legend must be provided for each igure Oversized original illustrations should be hotographed and a print on glossy paper submitted A separate *title page* is necessary and should bear) the title b) the initials and names of the authors) the institution of origin Below the list of references he principal author should state his address to which he proofs are to be sent

A short *abstract* not exceeding 200 words must ccompany each manuscript informing about problem methods results and conclusions Unexplained bbreviations and references are not allowed The bstract must be typed on a separate sheet and styled s illustrated

G H Valentine *The chromosome disorders An introduction for clinicians* 3rd ed William Heinemann Medical Books Ltd London 1976 184 pp illus £5 00

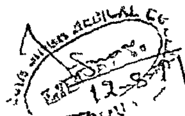
This book is written by the professor of paediatrics at the University of Western Ontario Canada and dedicated to Dr Barr of the same university who initiated the science of clinical cytogenetics by his discovery of the X chromatin (Barr) body in 1949 This book is a well written brief review divided into two parts Part I The grammar of cytogenetics and Part II The chromosome diseases

The strength of the book lies firstly in the fact that the author is writing from extensive personal practical clinical and cytogenetical experience and secondly in the excellent illustrations The author has written in a narrative even conversational and humorous style The presentation progresses step by step from the biological facts to the more complex clinical picture

This is a book which one would especially recommend paediatricians in training

Karl Henrik Gustavson

Gordon Brocklehurst (ed) *Spina bifida for the clinician* Clinics in Developmental Medicine No 57 Spastics International Medical Publications William Heinemann Medical Books Ltd London 1976 195 pp illus £5 50



D Forrest W J W Sharrard and G Stark are the wellknown co authors of this new monograph dealing with the complex care of the child with spina bifida The vast experience of these authorities from Great Britain guarantees the high quality of the material presented and the solid foundation for the opinions expressed The outstanding chapter on the general paediatric management by Stark contains much good advice on how to handle the patient and the parents in the common difficult situations The special section on the management of bladder and bowel by Forrest is also a valuable guide for the physician directly involved in the care of spina bifida children The advice to treat mild cases of recurrent symptomatic urinary infections with a small dose of a suitable drug at bedtime is however based on a study of urinary tract infections in adults with non neurogenic bladder disturbances and is hardly valid for the child with myelomeningocele

The tremendous experience by Sharrard is reviewed in his chapter on the general and specific orthopaedic management What one is perhaps missing in this as well as in almost all other monographs on spina bifida is a section containing physiotherapy and physical training in general which is of greater importance than many physicians realize The original work of the editor on the pathology of spina bifida and the associated hydrocephalus as well as the relationship of pathological lesions to clinical manifestations is extensively presented perhaps a little out of proportion for a volume of this character The book ends with a survey of the results of treatment and of the selection of the type of treatment and it is pointed out that the *difficult decision to operate or not should be made individually* for each patient and should not be just a result of gross categorization

EDITORIAL

A SWEDISH CODE OF ETHICS FOR MARKETING OF INFANT FOODS

A decline of breast feeding has been observed as a world wide phenomenon in recent decades Most unfortunately this tendency has spread to large population groups which like the urban slum dwellers of Third World countries lack even the basic requirements (finance hygiene education etc) for successful artificial feeding at an early age

This development has caused growing concern among health professionals as well as in various organizations working in the health and nutrition field At the World Food Conference in Rome in 1974 (8) Resolution V dealt with this problem The following recommendation is a quotation of item 5 6

> That governments consider the key role of women and take steps to improve their nutrition their educational levels and their working conditions and to encourage them and enable them to breast feed their children

The underlying reasons for the decline in breast feeding in many parts of the world are diverse and complex Some of the major ones are social change (the extended family giving way to the two-generation one) desire for independence increased engagement of women in professional work outside the home inexperience and inertia of health personnel attraction of breast milk substitutes promoted through unduly persuasive advertising An additional contributory factor especially in the Third World countries is the example set by members of higher social classes who mimic Western behavioral patterns

In this context only the adverse effects of unhampered promotion of industrially produced infant formulas will be dealt with This problem complex has attracted increasing attention during the 1970 s

A consecutive series of meetings between representatives of the infant food industry and paediatricians has been organized under the auspices of the UN Protein Calorie Advisory Group (PAG) The most recent outcome of these deliberations is found in PAG Bulletin 1975 V 1 (6) Recently the infant food industry itself has taken the initiative of organizing an International Council of Infant Food Industries (3) which has presented its own code of ethics

In addition to the above other bodies have commented in more general terms upon the ethics of promotion of infant foods Thus at the 13th International Congress of Pediatrics in Vienna 1971 the International Pediatric Association (IPA) organized a fullday work shop on New urban families (4) which among its recommendations included the following

> Realizing the paramount importance of good nutrition during early life especially during the first six months and that under the conditions prevailing among underprivileged groups in developing countries it is extremely difficult to substitute any suitable food for breast milk the formula producing food companies should observe great caution in applying methods of promoting their products They (persons contacting mothers) should never use their influence to promote a particular product in such a way that it could be detrimental to good breast feeding practices

Likewise WHO at the 27th World Health Assembly in 1974 in a Statement on Infant Nutrition and Breast feeding (2)

Urges member countries to review sales promotion activities on baby foods and to introduce appropriate remedial measures including advertisement codes and legislation where necessary

And more recently at an IPA seminar at Montreux (August 1975) for paediatricians from N Africa and Middle East Recommendations for Action Programs to encourage Breast feeding were adopted (7), these also including a section Curtailing Promotion of Artificial Feeding which deserves to be quoted in extenso

Sales promotion activities of organizations marketing baby milks and feeding bottles that run counter to the general intent expressed in this document must be curtailed by every means available to the profession including where necessary and feasible legislation to control unethical practice

Dissemination of propaganda about artificial feeding and distribution of samples of artificial baby foods in maternity units should be banned immediately

It is quite obvious that we are still far from achieving a proper balance between what can be regarded as acceptable business activities on the one hand and social and nutritional considerations on the other No wonder then that the multinational corporations in the infant food business have been subject to growing criticism (1)

In this period when the marketing ethics of the infant food industry are under sharp scrutiny it would seem that any relevant experience of attempts to monitor the activities in this field is worth imparting to a wider circle This Journal has therefore deemed it of interest to present the following document Medical standards for marketing of infant foods , which was worked out in Sweden as early as in 1964 as a guide to the infant food industries

Instrumental in preparing this code was a group of paediatricians the majority of them professors of paediatrics at Swedish universities As consultants to the two leading Swedish infant food industries they have been in the position to monitor the implementation of the code It can be clearly stated that the code has not remained just a pious declaration It has indeed been pivotal in avoiding aberrations detrimental to the consumer

On the whole the Swedish industries concerned should be given great credit for having shown a clear ambition to follow the standards laid down in the code thus proving their understanding for the concern of the paediatricians and the need of a marketing approach which does not undermine the mothers interests in breast feeding their children

In 1975 some slight revisions of the code were introduced but basically and in all its salient points the revised edition which is presented below closely follows the original one

It may be of some interest to note that the rules laid down in the Swedish code and the marketing procedures thus adhered to are much more detailed and strict than those in any of the codes or recommendations discussed above The consequences of unethical marketing in Third World countries are potentially more harmful than in a Scandinavian country Thus it would seem that the standards of the Swedish code adapted to the situation of Third World countries would form a sound basis for the discussion of their needs

Third World countries also need to have access to infant formulas—industrially produced or not—for those infants who suffer from a definite undernutrition at the breast As long as the undernutrition is of a mild degree it is however certainly better not to interfere For children from the dominating groups of poor families it is better to be exposed to a period of slight undernutrition than to run the risk of infections and diarrhoeal diseases following administration of formulas Further in industrial countries semisolid and solid baby food (so called Beikost) is normally recommended to be introduced at 3–4 months but in Third World countries for the reasons just mentioned it should rather be started at 6 months if breast feeding is reasonably satisfactory

But then we have also in Third World coun

tries mothers who at an early stage and in spite of a strong motivation to breast feed dry up In these cases and if a wet nurse cannot be recruited the infants must be given some kind of formula sometimes before the age of 6 months These babies should be carefully supervised by the local health centre The formula to be used in these cases should preferably be of a simple milk based nature or possibly some kind of stretch the milk type (mainly vegetable) product (5) In either case the procurement of such an infant food would be beyond the means of a poor family Thus the survival of the child will be largely dependent on institutional feeding programme with free distribution through proper health service channels

It must be acknowledged that such programmes with free distribution of infant formula products commercial or non commercial (through government national and international voluntary organizations etc) must be carried out in a very careful way if they are not to come rightly under the same criticism as the baby food industry *It is true that the financial* problem may be thus overcome but they may lead to a flooding with formula products a displacement of breast feeding and all the risks of contamination that prevail under unhygienic environmental conditions This aspect of institutional infant feeding programmes has been given too little attention in the past

MEDICAL STANDARDS FOR MARKETING OF INFANT FOODS IN SWEDEN[1,2]

Version Released by a Group of Swedish Paediatricians 1975[3]

1 Advertisements for and information concerning infant foods should always be in a form which is concordant with the views on infant feeding held by the medical consultants of the firms in question

2 Advertisements for breast milk substitutes (starting infant formulas) should in no form be aimed directly towards the public or towards individual families Special discount offers to the consumer should not be made with regard to products of this type

3 Advertisements sent directly to the individual family for other infant foods such as fruit juices baby drinks strained and junior foods follow up formulas and similar foods should not be distributed so that they reach the consumer before the child is about 3 months old

---

[1] The standards correspond essentially to the code of ethics in this field laid down originally by a group of Swedish paediatricians in 1964

[2] It should be noted that in Sweden no advertising takes place on television or radio

BILIRUBIN DISPLACING EFFECT OF STABILIZERS ADDED TO INJECTABLE PREPARATIONS OF HUMAN SERUM ALBUMIN

ROLF BRODERSEN and POUL HANSEN

From the Institute of Medical Biochemistry University of Aarhus Aarhus Denmark and Statens Seruminstitut Copenhagen Denmark

ABSTRACT Brodersen R and Hansen P (Institute of Medical Biochemistry Aarhus University Aarhus and Statens Seruminstitut Copenhagen Denmark) Bilirubin displacing effect of stabilizers added to injectable preparations of human serum albumin Acta Paediatr Scand 66 133 1977.—Stabilizers added to preparations of human serum albumin before heat treatment were tested for bilirubin displacing effect using the peroxidase method It was found that N-acetyltryptophan and sodium caprylate displace bilirubin from its complex with human serum albumin *in vitro* The quantitative findings were used for a rough estimate of the effect of these substances on the free bilirubin concentration in blood plasma expected when stabilized albumin preparations are given intravenously for prevention of kernicterus The calculated effect is a delay of the decrease of free bilirubin concentration or even a temporary increase Sodium mandelate displaces less strongly

KEY WORDS Albumin bilirubin displacement fatty acids kernicterus stabilizers

Human serum albumin is often used before or during exchange transfusion in prevention of kernicterus The amount of bilirubin removed from the body is substantially increased if an intravenous dose of albumin is given 1–2 hours before exchange (7) In the manufacture of injectable albumin preparations stabilizers are added to protect the protein during heat treatment 10 hours at 60° used to prevent transmission of hepatitis virus Accepted stabilizers are the sodium salts of N acetyltryptophan or caprylic acid or a mixture of both in a total concentration of 0 04 mol/l (6 8) Sodium mandelate has been used elsewhere to a limited extent The possible effect of giving these compounds together with the albumin has received little attention It has previously been shown (2) that N acetyltryptophan may displace bilirubin *in vitro* from its complex with serum albumin The present work extends these investigations to the other two stabilizers The results are used for a tentative calculation of the effect of these substances on the concentration of free bilirubin in the blood plasma

MATERIALS AND METHODS

Human serum albumin was from KABI Sweden This preparation does not contain added stabilizers and has not been heated The peroxidase method was used as previously described (?) to measure bilirubin displacing effect

RESULTS

The results are seen in Fig 1 The graph shows the velocity of oxidation of bilirubin 15 μmol/l with hydrogen peroxide and peroxidase in the presence of human serum albumin 30 μmol/l This velocity increases with the concentration of added stabilizer indicating

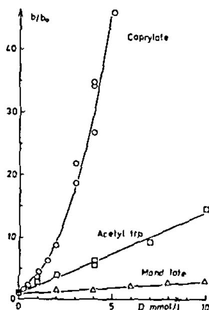

Fig 1 Displacing effect of stabilizers on bilirubin bound to human serum albumin measured by the peroxidase method (2) Ordinate relative rate of oxidation of bilirubin This is proportional to the free i e non protein bound bilirubin concentration Abscissa concentration of the displacer in the reaction mixture Bilirubin concentration was 15 μmol/l human serum albumin 30 μmol/l phosphate buffer 60 mmol/l pH 7 4 37 O Sodium caprylate □ N acetyltryptophan sodium salt Δ sodium mandelate

that albumin bound bilirubin is made available to oxidation by the enzyme In case of simple competitive displacement of bilirubin by the added substance a straight line is obtained (2) as seen for N acetyltryptophan and mandelate The curved line for caprylate indicates that a more complicated mechanism is operative with high concentrations of this substance possibly involving a conformational transition of the albumin molecule Control experiments carried out in the absence of albumin, showed that none of the stabilizers reacted directly with bilirubin nor with the reagents used in the test The free bilirubin concentration is therefore proportional to the oxidation velocity and can in relative terms be read from the ordinates of the curves

It is seen that all three substances displace bilirubin to some extent from its binding to human serum albumin The effect increases in the order mandelate acetyltryptophan caprylate

DISCUSSION

The possible significance of these findings when stabilized albumin preparations are used in the treatment of icteric neonates for prevention of kernicterus may be roughly estimated as follows

An albumin dose of 1 g/kg given as a 20% solution with 40 mmol/l N acetyltryptophan to an infant with a plasma volume of 40 ml/kg would give an added albumin concentration about 340 μmol/l and an initial concentration of 4 4 mmol/l of the stabilizer when mixed completely with the blood plasma Most of the stabilizer about 4 mmol/l would be present as non protein bound N acetyltryptophan and would as seen from the figure cause a 6 fold increase of free bilirubin concentration This would be counteracted by binding of bilirubin to the albumin given The magnitude of the latter effect would vary with the concentrations of bilirubin and albumin before treatment Since the free bilirubin concentration is inversely proportional to the molar surplus of albumin over bilirubin and if the concentration of albumin is between 27 and 30 g per liter (410 to 450 μmol/l) and bilirubin is from 18 to 22 mg per 100 ml (310 to 380 μmol/l) the molar surplus of albumin ranges from 30 to 140 μmol/l before treatment and from 370 to 480 μmol/l after the albumin dose The albumin surplus accordingly increases by a factor roughly between 3 and 12 and the free bilirubin concentration decreases by a factor between 3 and 12 as a result of giving albumin alone The total outcome after giving N acetyltryptophan and albumin together is therefore likely to range from an increase of free bilirubin concentration by a factor 2 to a decrease to half of the level before treatment During a period of time after the injection the stabilizer is eliminated from the blood stream and a decrease of free bilirubin concentration may be expected

Sodium caprylate is a salt of a medium chain fatty acid Its strong effect in the experimental procedure is moderated *in vivo* by binding to the albumin molecule where it is mostly ac

comodated in sites which do not bind bilirubin As estimated from the binding isotherm published by Ashbrook et al (1) about 70% is protein bound at the actual concentration level This means that the displacement caused by caprylate in the blood plasma would be of the same order of magnitude as that of N acetyltryptophan Special caution is however indicated with this substance if increased amounts of fatty acids are already present before treatment As shown by Ashbrook et al binding of caprylate is decreased by the presence of long chain fatty acids The concentration of these is often somewhat elevated in newborns (3) and may be very high in case of generalized infection (4) or after use of intravenous lipid preparations for parenteral nourishment (5 10) The steep curvature of the line in Fig 1 suggests a potentiated effect of high concentrations of fatty acids in agreement with previous observations (9) Also slow elimination in a premature child already loaded with fatty acids would further delay the onset of the bilirubin binding process

Mandelate displaces considerably less The efficiency of this substance as a stabilizer and the possible pharmacological effects of the large doses in question have not been investigated in sufficient detail

In conclusion determination of the bilirubin displacing effect of stabilizers *in vitro* seems to indicate that N acetyltryptophan and caprylate if present in permitted amounts in injectable preparations of human serum albumin may cause a delay or even a temporary reversal of the bilirubin binding effect of the albumin given Removal of the stabilizers before dispensing would result in preparations without potential bilirubin-displacing capability and presumably with a more prompt bilirubin binding effect The capability of the preparations to bind bilirubin could be tested by the peroxidase method Such testing would further ensure that the full effect of the albumin has been restored after heat treatment

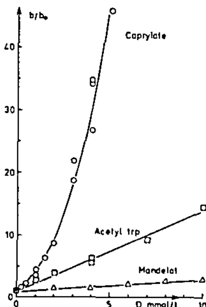

Fig 1 Displacing effect of stabilizers on bilirubin bound *to human serum albumin measured by the peroxidase* method (2) Ordinate relative rate of oxidation of bilirubin This is proportional to the free i e non protein bound bilirubin concentration Abscissa concentration of the displacer in the reaction mixture Bilirubin concentration was 15 µmol/l human serum albumin 30 µmol/l phosphate buffer 60 mmol/l pH 7 4 37 O Sodium caprylate □ N acetyltryptophan sodium salt Δ sodium mandelate

that albumin bound bilirubin is made available to oxidation by the enzyme In case of simple competitive displacement of bilirubin by the added substance a straight line is obtained (2) as seen for N acetyltryptophan and mandelate The curved line for caprylate indicates that a more complicated mechanism is operative with high concentrations of this substance possibly involving a conformational transition of the albumin molecule Control experiments carried out in the absence of albumin showed that none of the stabilizers reacted directly with bilirubin nor with the reagents used in the test The free bilirubin concentration is therefore proportional to the oxidation *velocity and can in relative terms* be read from the ordinates of the curves

It is seen that all three substances displace bilirubin to some extent from its binding to human serum albumin The effect increases in the order mandelate *acetyltryptophan* capry late

DISCUSSION

The possible significance of these findings when stabilized albumin preparations are used in the treatment of icteric neonates for prevention of kernicterus may be roughly estimated as follows

An albumin dose of 1 g/kg given as a 20% solution with 40 mmol/l N acetyltryptophan to an infant with a plasma volume of 40 ml/kg would give an added albumin concentration about 340 µmol/l and an initial concentration of 4 4 mmol/l of the stabilizer when mixed completely with the blood plasma Most of the stabilizer about 4 mmol/l would be present as non protein bound N acetyltryptophan and would, as seen from the figure cause a 6 fold increase of free bilirubin concentration This would be counteracted by binding of bilirubin to the albumin given The magnitude of the latter effect would vary with the concentrations of bilirubin and albumin before treatment Since the free bilirubin concentration is inversely proportional to the molar surplus of albumin over bilirubin and if the concentration of albumin is between 27 and 30 g per liter (410 to 450 µmol/l) and bilirubin is from 18 to 22 mg per 100 ml (310 to 380 µmol/l) the molar surplus of albumin ranges from 30 to 140 µmol/l before treatment and from 370 to 480 µmol/l after the albumin dose The albumin surplus accordingly increases by a factor roughly between 3 and 12 and the free bilirubin concentration decreases by a factor between 3 and 12 as a result of giving albumin alone The total outcome after giving N acetyltryptophan and albumin together is therefore likely to range from an increase of free *bilirubin concentra*tion by a factor 2 to a decrease to half of the level before treatment During a period of time after the injection the stabilizer is eliminated from the blood stream and a decrease of free bilirubin concentration may be expected

Sodium caprylate is a salt of a medium chain fatty acid Its strong effect in the experimental procedure is moderated *in vivo by binding to* the albumin molecule where it is mostly ac

comodated in sites which do not bind bilirubin As estimated from the binding isotherm published by Ashbrook et al (1) about 70% is protein bound at the actual concentration level This means that the displacement caused by caprylate in the blood plasma would be of the same order of magnitude as that of N acetyltryptophan Special caution is however indicated with this substance if increased amounts of fatty acids are already present before treatment As shown by Ashbrook et al binding of caprylate is decreased by the presence of long chain fatty acids The concentration of these is often somewhat elevated in newborns (3) and may be very high in case of generalized infection (4) or after use of intravenous lipid preparations for parenteral nourishment (5 10) The steep curvature of the line in Fig 1 suggests a potentiated effect of high concentrations of fatty acids in agreement with previous observations (9) Also slow elimination in a premature child already loaded with fatty acids would further delay the onset of the bilirubin binding process

Mandelate displaces considerably less The efficiency of this substance as a stabilizer and the possible pharmacological effects of the large doses in question have not been investigated in sufficient detail

LONG TERM EFFECT ON MOTHER–INFANT BEHAVIOUR OF EXTRA CONTACT DURING THE FIRST HOUR POST PARTUM

I *First Observations at 36 hours*

PETER DE CHATEAU and BRITT WIBERG

From the Departments of Paediatrics and Child Psychiatry University of Umeå Umeå Sweden

ABSTRACT de Chateau P and Wiberg B (Department of Paediatrics and Department of Child Psychiatry University of Umeå Umeå Sweden) Long term effect on mother–infant behaviour of extra contact during the first hour post partum I First observations at 36 hours Acta Paediatr Scand 66 137 1977.—The immediate post partum period may be particularly important for the developing relationship between mother and infant little is as yet known however of the long term effects of hospital practice during this period This study examines the effect of extra contact during the first hour following delivery An extra skin to skin contact and suckling contact was given to 22 primiparous mothers and their infants One control group of 20 primiparous mothers and infants and a second one of 20 multiparous mothers and infants was given routine care immediately after birth All mothers and infants were healthy with normal pregnancies and deliveries At 36 hours a first observation was made of maternal and infant behaviour during breast feeding in all three groups At this stage primiparae with extra contact showed behaviour much more like the behaviour of multiparae with routine care Infants of primiparae with routine care cried most frequently The behaviour of mothers of boys differed more from group to group than did that of mothers of girls

KEY WORDS Mother–infant behaviour extra contact neonatal period observations

An extended contact between mother and infant during the first post partum days may influence development of mother–infant interaction and attachment (4 6) Klaus et al (4) in their study gave to 14 mothers one hour of close physical contact with their nude fullterm infants within the first three hours after delivery and another 15 extra hours of contact in the first three days post partum (extended contact) a control group of mothers was given routine contact with their newborn babies In follow up studies one month (4) one year (5) and two years (16) after delivery differences between the extended contact and the control group were found with regard to maternal attachment behaviour and linguistic behaviour Maternal and infant behaviour is controlled by many other factors than early physical contact only Prenatal influences like the mother s relationship with her own mother (12) and the infant s father her cultural background planning and preparations for pregnancy delivery and so on may be of great importance and must therefore be checked when studies of the impact of changes in the immediate post partum period on maternal and infant behaviour are presented

In this study we have examined what effect extra contact limited to 15 min immediately following delivery might have on mother and infant behaviour Three groups of mother–infant pairs were studied 22 primiparae and their infants with during the first hour after delivery extra naked skin to skin and suck

METHODS

Routine care immediately following delivery (P and M groups)

After delivery the baby lies on the delivery table between the legs of the mother Mouth and upper airways are rinsed and the stomach emptied Face trunk and legs are wiped dry with a towel The infant is then shown to the mother for a brief glance but usually she does not touch him A numbered bracelet is put around the wrist of both mother and infant After cord clamping 2–6 min post partum the baby is taken to another part of the delivery room for weighing bathing physical examination Crede prophylaxis and dressing This takes approximately 30 min In the meantime the mother is helped to deliver the placenta washed and cleaned The baby—with clothes on—is put in a crib and covered with a blanket The crib is placed beside the mother s bed so that she can watch her baby and touch the face In some instances the baby dressed and wrapped in a blanket is placed in the mother s bed The mother the infant and the father who has often attended the delivery of the infant stay together in the delivery room until approximately 2 hours after the actual time of birth when they are transferred to the maternity ward

Extra contact immediately following delivery (P+ group)

Mouth and upper airways are rinsed the stomach emptied the body dried with a towel and a numbered bracelet fastened around the wrists of infant and mother as in routine care After clamping of the cord 2–6 min following delivery the midwife puts the naked baby onto the mother s abdomen and the infant s back is covered with a blanket This skin to skin contact begins approximately 10 minutes post partum Some five minutes later the midwife moves the baby upwards onto the mother s chest and helps him to suckle from his mother s breast i e approximately 15 min post partum (Fig 1) This extra contact lasted for about 10 to 15 min After this period when the baby was about 25–30 min old the normal routine procedure as described above was continued

Routine care at the maternity ward from about 2 hours after delivery until discharge from hospital 6–8 days later (P+ P and M groups)

During the first three days the mother sees and nurses her infant every 4 hours during the day The infant stays during the night and most of the day in a separate baby room During the second half of the post partum week the infant stays during the daytime in his mother s room The mother takes a more active part in the care of her infant giving him a bath changing nappies and clothes and so on In most rooms there is accommodation for four mothers and their infants

Observations of mother and infant behaviour

Before leaving the delivery floor the mothers were asked to participate with their infants in an ongoing study and told that observation was going to take place later on in the maternity ward None of the mothers refused probably because the approach was via the midwives who by that time were well known to and trusted by the mothers Observation of all subjects was made about 36 hours after delivery (range 32–40 hours) in the mother's own room during breast feeding Two observers participated in the study and the subjects were randomly assigned to one of them They did not know to which group the mother–infant pairs belonged Only one observer was present at each observation All mothers were in a 4-bed room During the observation the other mothers in this room were nursing their own babies as usual The position of the mother her infant and the observer is shown in Fig 2 The observer was present in the room a few minutes before the infant was brought in so as to be less obtrusive Observation started immediately the infant s crib was brought into the mother's room No conversation between mother and observer was allowed during the observation Thirty-five different behavioural items[1] were scored and noted on a check sheet

The observation period was 15 min divided into 20 periods of 15 sec actual observation and 20 periods of 30 sec for writing down on the check-sheet all that had happened during the previous 15-sec period A small tape recorder provided signals through an ear microphone to indicate the observation and writing periods The use of this apparatus was explained to the mothers before the actual observation was started Behaviour that occurred during that period was scored as 1 At the end of the observation the score for every item of behaviour was added up and the total was used as a measure of frequency of the particular behaviour during the observation The maximum score for any item was therefore 20 Behaviour not included in our observation sheet did sometimes occur

Fig 2 The position of the mother the infant and the observer during the observation at 36 hours post partum

---

[1] They were defined in co-operation with Mary Anne Trause and based mainly on experience gained in studies performed at the Department of Paediatrics Case Western Reserve University Cleveland USA (Head Marshall H Klaus) Complete data on selection drop-out definitions of the behavioural items the check sheet and detailed results of all observations can be obtained on request from the principal author

Fig 1 a and b The extra skin to skin contact and suckling contact

ling contact 20 primiparae and their infants with the usual routine care after delivery and 20 multiparae and infants with routine care At 36 hours observation was made of maternal and infant behaviour during breast feeding The difference in experimental conditions between Klaus et al and this study is that they studied the impact of early and extended contact, while we only studied the impact of extra contact immediately following delivery (early contact) on maternal behaviour Furthermore we looked at infant behaviour

This paper is the first report of a longitudinal study in which the impact on the mother to infant relationship of this extra contact immediately after delivery will be studied at different times and by means of various techniques such as direct observations medical check ups interviews and studies of infant development

MATERIAL

The study included 62 mother-infant pairs divided into three groups

1 *P+* group Primiparous women (n=22) given Extra contact with their newborn infants followed by Routine Care
2 *P* group Primiparous women (n=20) given Routine Care with their newborn infants
3 *M* group Multiparous women (n=20) given Routine Care with their newborn infants

Selection criteria The basic principle for participation in the study was that mothers and infants should be healthy and live in the Umeå area and that pregnancy and delivery should have been normal The groups were comparable as to mean maternal age social categories education civil state mean number of visits to antenatal clinic and maternal weight gain during pregnancy An equal proportion of the fathers was present at delivery the mean duration of labour and amount of analgesia used were comparable in the two groups of primiparae whereas shorter duration of delivery and less use of analgesia during labour was observed for the *multiparae* The number of breastfeedings before the actual observation and time of observation after delivery did not differ between the three groups Other criteria that all mother-infant pairs had to meet were no history of previous abortions or miscarriages no use of drugs except iron medication and vitamins during pregnancy normal weight gain (14) normal blood pressure and Hb-percentage and no proteinuria (13) The mother should have come into labour spontaneously at fullterm All infants should have been born in vertex presentation and have had no signs of intra or extra uterine asphyxia There had to have been no signs or symptoms of congenital malformation or disease at physical examination 1 day and 6 days post partum Many of these criteria are described by Prechtl et al (15) as optimal obstetrical conditions and others have been used by Thoman et al (18)

Selection procedure The midwives made a preliminary selection of the mothers to study when they arrived at the hospital for delivery and allocated them to one of the above mentioned groups At this point mothers and midwives were not familiar with each other This preliminary selection was thus solely based on existing data concerning previous obstetric history present pregnancy and residence within the Umeå area By this preliminary procedure 74 mother-infant pairs were selected for the study Twelve mother-infant pairs who did not fulfil the established criteria concerning residence delivery infant and neonatal period were excluded The final study groups thus comprised 62 mother-infant pairs

METHODS

Routine care immediately following delivery (P and M groups)

After delivery the baby lies on the delivery table between the legs of the mother Mouth and upper airways are rinsed and the stomach emptied Face trunk and legs are wiped dry with a towel The infant is then shown to the mother for a brief glance but usually she does not touch him A numbered bracelet is put around the wrist of both mother and infant After cord clamping 2–6 min post partum the baby is taken to another part of the delivery room for weighing bathing physical examination Credé prophylaxis and dressing This takes approximately 30 min In the meantime the mother is helped to deliver the placenta washed and cleaned The baby—with clothes on—is put in a crib and covered with a blanket The crib is placed beside the mother s bed so that she can watch her baby and touch the face In some instances the baby dressed and wrapped in a blanket is placed in the mothers bed The mother the infant and the father who has often attended the delivery of the infant stay together in the delivery room until approximately 2 hours after the actual time of birth when they are transferred to the maternity ward

"Extra contact" immediately following delivery (P+ group)

Mouth and upper airways are rinsed the stomach emptied the body dried with a towel and a numbered bracelet fastened around the wrists of infant and mother as in routine care After clamping of the cord 2–6 min following delivery the midwife puts the naked baby onto the mother s abdomen and the infant s back is covered with a blanket This skin to skin contact begins approximately 10 minutes post partum Some five minutes later the midwife moves the baby upwards onto the mother s chest and helps him to suckle from his mother s breast i e approximately 15 min post partum (Fig 1) This extra contact lasted for about 10 to 15 min After this period when the baby was about 25–30 min old the normal routine procedure as described above was continued

Routine care at the maternity ward from about 2 hours after delivery until discharge from hospital 6–8 days later (P+ P and M groups)

During the first three days the mother sees and nurses her infant every 4 hours during the day The infant stays during the night and most of the day in a separate baby room During the second half of the post partum week the infant stays during the daytime in his mother s room The mother takes a more active part in the care of her infant giving him a bath changing nappies and clothes and so on In most rooms there is accommodation for four mothers and their infants

Observations of mother and infant behaviour

Before leaving the delivery floor the mothers were asked to participate with their infants in an ongoing study and told that observation was going to take place later on in the materni ty ward None of the mothers refused probably because the approach was via the midwives who by that time were well known to and trusted by the mothers Observation of all subjects was made about 36 hours after delivery (range 32–40 hours) in the mother's own room during breast feeding Two observers participated in the study and the subjects were randomly assigned to one of them They did not know to which group the mother–infant pairs belonged Only one observer was present at each observation All mothers were in a 4-bed room During the observation the other mothers in this room were nursing their own babies as usual The position of the mother her infant and the observer is shown in Fig 2 The observer was present in the room a few minutes before the infant was brought in so as to be less obtrusive Observation started immediately the infant s crib was brought into the mother's room No conversation between mother and observer was allowed during the observation Thirty five different behavioural items were scored and noted on a check sheet

Fig 2 The position of the mother the infant and the observer during the observation at 36 hours post partum

The observation period was 15 min divided into 20 periods of 15 sec actual observation and 20 periods of 30 sec for writing down on the check-sheet all that had happened during the previous 15-sec period A small tape recorder provided signals through an ear microphone to indicate the observation and writing periods The use of this apparatus was explained to the mothers before the actual observation was started Behaviour that occurred during that period was scored as 1 At the end of the observation the score for every item of behaviour was added up and the total was used as a measure of frequency of the particular behaviour during the observation The maximum score for any item was therefore 20 Behaviour not included in our observation sheet did sometimes occur

They were defined in co-operation with Mary Anne Trause and based mainly on experience gained in studies performed at the Department of Paediatrics Case Western Reserve University Cleveland USA (Head Marshall H Klaus) Complete data on selection drop-out definitions of the behavioural items the check sheet and detailed results of all observations can be obtained on request from the principal author

Table 1 *Maternal and infant behaviour during breast feeding on the second day of life*

Figures denote mean frequency of behaviour during the twenty 15 sec observation periods $P+$=primiparous mothers and infants with extra contact P=primiparous mothers and infants with routine care M=multiparous mothers and infants with routine care

Observation	Mean frequencies			*p* Values		
	P+ (*n*=22)	*P* (*n*=20)	*M* (*n*=20)	*P*+/*P*	*P*+/*M*	*P*/*M*
Mo lying down	8 1	9 2	3 2		0 04	0 02
Mo leaning on elbow	2 4	7 9	3 5	0 02		0 08
Mo sitting up	10 1	3 3	13 6	0 009	0 2	0 003
Infant crying	1 0	2 4	0 5	0 2		0 03
Holds infant	10 9	2 9	11 7	0 001		0 0005
Encompassing	9 3	5 3	10 9	0 1		0 03

Some of this was noted but none of it could be used during data analyzing

Inter observer reliability

The two observers were compared before as well as after the study proper Each of these reliability studies comprised 8 mother–infant pairs The observation was—as in the study—performed during an ordinary breast feed These mothers and infants did not meet any specific criteria other than that pregnancy delivery and the first post partum days had been normal The mothers had agreed to the presence of two observers The correlation coefficient (r) was above 0 90 for all of the 35 behavioural items both before and after the study proper

Statistical methods

For every item observed the mean frequency for each of the three observation groups ($P+$ P and M) was calculated The t test was used in analyzing these results and p values given were obtained by this method $p<0\ 05$ is regarded as significant

RESULTS

1 *Mother–infant behaviour at 36 hours Comparison of groups P+, P and M*

Primiparous mothers with extra contact differed in a highly significant way from those with routine care in three of the 35 items observed two of which were mutually exclusive (Table 1) Multiparous women with routine care differed in only one instance from primiparous women with extra contact but in five from primiparae with routine care The mother s position differed greatly between the three groups during the observation $P+$ and M mothers were sitting up more frequently while P mothers were lying down or leaning on one elbow more often $P+$ and M mothers held heir infants more often than did P mothers Encompassing which could occur both when mothers were sitting and when they were lying down was observed twice as often in $P+$ as in P mothers although this difference was not significant Similarly M mothers were encompassing their infants significantly more than P mothers Infants of P mothers were crying significantly more frequently than infants in the M group and twice as often as $P+$ infants

2 *Mother–infant behaviour by sex of infant within each of the three groups P+ P and M*

The most marked differences were found within the $P+$ group (Table 2) Mothers in this group were holding male infants significantly more often made more attempts to burp their male infants showed more encompassing smiled and looked en face more frequently at boys The $P+$ mothers talked more often to their girls The differences within the P group by sex of infant were much less pronounced significant only for infant on knees and encompassing which was more common in mothers with females Within the M group no prominent differences were seen in maternal or infant behaviour when mothers with males and females were compared

Table 2 *Behaviour differences by sex of infant within the three groups (P+ P and M)*

P+=primiparae with extra contact P=primiparae with routine care M=multiparae with routine care

Observation	P+ group (12♂–10♀) p values	P group (13♂–7♀) p value	M group (10♂–10♀) p value
Burps	0 04	0 2	–
Infant on knees	–	0 05	–
Holds	0 07	0 08	–
Encompassing	0 07	0 01	–
En face	0 04	0 07	–
Talks to infant	0 01	0 08	–
Smiles at infant	0 07	0 2	–

3 *Mother–infant behaviour by care and parity groups P+ P and M within each sex*

Mothers with male infants P+ mothers were *sitting up holding and encompassing* their boys with close body contact significantly more often than P mothers (Table 3) The P+ mothers also made more frequent attempts to let their boys burp P+ infants were significantly less quiet than M infants Like the P+ mothers with male infants M mothers were *sitting up* significantly more often than P mothers male infants in the P group were crying more frequently

Mothers with female infants No significant differences were found for P+ and P mothers and their female infants P+ mothers *with girls* were lying down significantly more often (p=0 006) *and talked less frequently* (p=0 03) to others than M mothers with girls No significant differences *were seen in maternal and infant* behaviour when comparison was made between P and M group with female infants

DISCUSSION

The results of the present study indicate that mothers with boys behave differently from mothers with girls although there has been the same immediate post partum care that differences in behaviour occur at 36 hours post partum between a group of mothers and infants who have had 15–20 min extra skin to skin and suckling contact immediately following delivery (P+) and a group of mothers and infants with routine care (P) that the influence of post partum care is greater on the behaviour of boys and their mothers than on girls and *their mothers Differences in behaviour be*tween primiparous and multiparous mothers and their infants were also found the differences being most pronounced between primis and multips with routine care and very small between primis with extra contact and multips with routine care At an interview with the mothers no differences were found between P+ and P mothers with regard to their relationship with their own mothers their husbands *planning of pregnancy* preparations for pregnancy delivery and baby or for percep

Table 3 *Behaviour mean frequencies and differences by care and parity within the infants of male sex*

tion of pregnancy, delivery and first post partum week It is thus not probable that such background factors could account for the observed differences in behaviour

The findings in $P+$ and P groups are similar to those reported by Klaus et al (4) in a study of 14 mother–infant pairs with and without extended contact The main difference between the two studies is that Klaus et al gave their babies one hour of naked contact following birth and in addition five extra hours with their mothers each afternoon of the three days after delivery while in the present study only 15–20 min of nude extra contact separated the two groups ($P+$ and P) The fact that this brought about the same effect gives emphasis to the opinion that the very first hours after delivery may be of the greatest importance If this is true man will fit into a pattern similar to that of all other mammals studied (7)

Klaus et al combined several behavioural items into groups (attachment behaviour for example) and could then obtain significant differences between care groups The present study extended these findings demonstrating significant differences even for individual behavioural items The fallacies in the methods used in studies of this kind are still incompletely explored and some points will therefore be discussed here Using 35 observational items one can expect some differences on the 5% level to occur by chance although some items excluded others More differences than could be expected by chance were found

Direct observation was preferred to filming although the presence of an observer is bound to have some effect (9) We found however that the observation session can be arranged as a fairly natural part of the care routine and we agree with Costello (3) that the flexibility of the human eye and brain far surpasses that of the camera In addition we found that a high inter observer reliability can be obtained Filming may be experienced as a less natural way of observation and even extensive re examination of film or video tape leaves many episodes ambiguous (3) Film observations are, however, certainly superior where intervals and sequences of behaviour are to be studied A one way screen is a third possible method which however, was not available to us

Differences in maternal behaviour during breast feeding depending upon parity have been reported by Thoman et al (17 18) primiparae spending more time in non feeding activities and changing activities In our study pronounced differences in maternal and infant behaviour were found between multiparae (M) and primiparae (P) primiparae with extra contact ($P+$) and multiparae (M) and their infants were however very much alike This may give further support to the opinion that extra contact influences maternal and infant behaviour

Studying visual alertness in certain neonates Korner & Thoman (8) found no differences between male and female infants but Leidermann et al (10) found differences in maternal behaviour depending on sex of infant Moss (11) found pronounced differences in both maternal and infant behaviour at three weeks boys sleeping less and crying more resulting in more extensive and stimulating interaction with the mother When the state of the infants was controlled most of these sex differences became weaker however The sex differences observed in our investigation thus have some support in earlier studies but extend these by showing that early contact had far more profound effects on boy–mother than on girl–mother pairs In the P+ mothers of boys were holding smiling (1) and making attempts to burp them more often while mothers of girls were talking to them more frequently Within the P group the differences correlated to sex of infant were much smaller mothers with girls having them more on their knees and encompassing Within the M group no significant differences were found

The eventual effects of extra neonatal contact on the relationship between mother and infant cannot be evaluated as yet but since we in a three months follow up study of $P+$ and P still do find differences in maternal and

even more in infant behaviour (2) the possibility exists that the extra post partum contact has a long term impact on the relationship between mother and infant Support for this may also ge given by the fact that early contact mothers ($P+$) breast fed for a longer period (2) In a number of follow-up studies one month (4) one year (5) and two years (16) after delivery Klaus et al also found differences in maternal behaviour between their extended contact group and control group The mere knowledge of the importance and possible positive effects of extra contact shortly after delivery may help to minimize the deleterious influence of necessary separation in cases of prematurity asphyxia malformation and the like A mother who refuses an extra contact offered to her may need to get support and help during her stay in the maternity ward Lastly the mode of neonatal care may be an important factor to take into account in studies of child development

LONG TERM EFFECT ON MOTHER–INFANT BEHAVIOUR OF EXTRA CONTACT DURING THE FIRST HOUR POST PARTUM

II A Follow up at Three months

PETER DE CHATEAU and BRITT WIBERG

From the Departments of Paediatrics and Child Psychiatry University of Umea Umea Sweden

ABSTRACT de Chateau P and Wiberg B (Department of Paediatrics and Department of Child Psychiatry University of Umeå Umeå Sweden) Long term effect on mother–infant behaviour of extra contact during the first hour post partum II A follow up at three months Acta Paediatr Scand 66 145 1977.—Primiparous mothers and their infants who had an extra 15–20 minutes suckling and skin to skin contact during the first hour after delivery behaved differently at 36 hours post partum compared with a control group without this extra contact The present study is a 3 month follow up of these mothers and infants by means of direct observation of mother–infant free play and a personal interview with the mothers Mothers in the extra contact group spent more time kissing and looking en face at their infants these infants smiled more often and cried less frequently A greater proportion of the mothers with extra contact were still breast feeding at 3 months The influence of extra contact on behaviour was more pronounced in boy–mother than in girl–mother pairs

KEY WORDS Mother–infant behaviour extra contact neonatal period follow up

Primiparous mothers and their infants who had had 15–20 min suckling and skin to skin contact (extra contact) during the first hour after delivery behaved differently at 36 hours post partum compared with a control group without extra contact (4) The differences were much greater for male infants and their mothers than for females

The two primiparous mother–infant groups (P+ and P) those with and those without extra contact have been observed at a home visit 3 months after delivery This follow up also included a personal interview with the mothers covering pregnancy neonatal week and the first 3 months after discharge from the maternity ward The results of the observation studies at 36 hours after delivery were not known to the observers at the time of the 3 month follow up study The results of the observational part will be presented and discussed in this paper in relation to other similar studies Some preliminary results of the personal interview will be given

The aim of the present study was to ascertain whether (*a*) there were any notable differences between infants of different sex with the same type of care and (*b*) whether changes in care had a different influence on female and male infants and their mothers

MATERIAL

All mothers were primiparous The study group mothers (P+) had had 15– 0 min suckling and skin to skin contact (extra contact) with their newborn babies during the first hour after delivery The control mother–infant pairs had had no such contact Otherwise the groups had been cared for in the same way The mother–infant pairs were randomly assigned to one of the two groups before delivery Details of selection and care have been described earlier (4) Background data were comparable in both groups (4) No differences between the two groups were

C

Fig 1 The approximate placement of mother (*A*) and infant (*B*) on the carpet (shaded area) and observer (*C*) during observations of free play at 3 months

found in the number of days the mother–infant had been staying in the maternity ward the mean infant weight loss during the neonatal period the number of contacts with the Child Health Centre the mean infant age at observation or the infant s postnatal growth and psychomotor development In both study group and control group one mother–infant pair participating in the first observation study (4) was lost on the present study One of the mothers was on holiday at the time of follow up and one had left the country for an extended stay abroad

METHODS

After completing the observation at 36 hours in the maternity ward (4) the observer talked to the mother and answered questions During this conversation we asked if we could contact her again for a follow up study when the infant was 3 months old All mothers agreed to this follow up The same two observers as earlier (4) participated in this study The appointments for home visits were made by a secretary The mother–infant pairs were thereafter randomly assigned to one of the two observers neither of them being aware of the group (*P*+ and *P*) to which the mother–infant pair concerned belonged The follow up study was done during a home visit and included a mother–infant free play observation A personal interview was held with the mothers This interview covered mother s perception of pregnancy delivery the neonatal week and first 3 months at home

Time of home visit

All home visits were made at 1 p m At this time most infants were asleep After an initial interview mother–infant free play approximately 2–2½ hours after the last feeding was observed This is a good time for observation (1) since the infant is usually alert and cooperative

Arrangements

The mother sat with the infant on the carpeted floor and the observer also sat on the floor approximately one metre away from them (Fig 1) Before the observation started the mother was told by the observer that we wanted to watch her and her infant during 10 min free play The mother was given a bell a dangling ring and a rattle bag (Fig 2) similar to those used in Gesell s Developmental Test (7) The mother could use the toys in whatever way and sequency she liked

Behavioural items

Sixty one different behavioural items were scored and noted on a check sheet most of which are very descriptive of what was observed [1]

Duration and technique of observation

During a pilot study we discovered that infants very soon got tired during observation The mean frequency for crying during observation of 8 infants was 0 25 during the first 5 min and 1 40 during the second 5 min period Similarly the mothers used a dummy test more frequently during the second half of the observation time than during the first half The observation periods were therefore kept as short as 10 min and good co-operation was obtained from all mother–infant pairs studied The observation period of 10 min was divided into 10 periods of 15 sec actual observation and 10 periods of 45 sec for writing down all that had happened during the previous 15 sec period Behaviour that occurred during that period was scored as 1 At the end of the observation the scores for all items of behaviour were added up and the total was used as a measure of the frequency of that particular behaviour during the observation The maximum score for any item was therefore 10 Behaviour not included on our observation sheet sometimes occurred Some of this was noted but none of it could be used during data analysis A tape recorder provided signals through an ear microphone to indicate the observation and writing periods

The use of this apparatus was known to the mothers from our first observation at the maternity ward (4) and if necessary re explained to the mothers before the observation started

Inter observer reliability

For reliability purposes a study was made of 11 mother–infant pairs during a routine 3 month check up at the

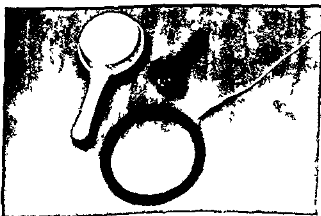

Fig 2 The bell dangling ring and rattle bag used during the observation of mother–infant free play

[1] Complete data on background definitions of the behavioural items the check sheet and the complete results of the observations can be obtained on request from the principal author

Child Health Centre in our hospital before the study proper started These mothers and infants did not meet any specific criteria other than that pregnancy delivery the first postnatal week at the maternity ward and the first 3 months at home had been normal they also agreed to participate in the reliability study and on the presence of two observers For none of the 61 items used during the observation the correlation coefficient (r) was lower than 0 9

Statistical methods

For every item observed the mean frequency for each of the two groups was calculated and the t test used in evaluating the level of significance The p values given are obtained by this method In the reliability study the correlation coefficient r was used

Table 1 *Primiparous mothers without extra contact (P)*

RESULTS

A *Observations of maternal and infant behaviour during free play*

The results of observations during the mother–infant free play are shown in Tables 1–5 First a comparison is made within groups with the same type of care but different sex of infant (Tables 1 and 2) Thereafter we present the results for different kind of care and compare for each sex separately (Tables 3 and 4) and finally make a comparison between groups with different post partum care as a grand total not relating to sex of infant (Table 5) Only those items of behaviour with p values in the t test of 0 08 or less are given in the Tables

Primiparous mothers without extra contact (P) comparison of behaviour with regard to sex of infant

Male infants had their eyes open during the entire observation period (Table 1) while female infants had their eyes closed during a part of the time observed (p=0 05) Consequently male infants were more alert and played with one of the three toys used (bell rattle dangling ring) during a greater proportion of the observation time (p=0 05) and mothers gave toys to boys to play with more often (p=0 08) Girls were crying somewhat more frequently and mothers cleaned them significantly more often (p=0 02) than boys

Primiparous mothers with extra contact (P+) comparison of behaviour with regard to sex of infant

Boys and girls were alert with eyes open during the entire observation period (Table 2) however male infants played more frequently with their hands (p=0 04) Mothers in both groups looked at their infants during the entire observation period mothers of boys spent a significantly longer proportion of their time in the en face position (p−0 04)

Primiparous mothers with extra contact (P+) and without extra contact (P) compared by sex of infants Boys

Mothers in the extra contact group (Table 3) looked en face (p=0 01) and kissed their boys significantly more often (p=0 01) they smiled

nity ward and felt that adaptation to their infants was somewhat more difficult More mothers in the extra contact group were still breast feeding their infants at 3 months than in the control group (6) Further details of the personal interview with the mothers will be published later (5)

DISCUSSION

The present study has shown that 3 months after delivery (1) maternal behaviour with boys and girls within groups with the same type of immediate postnatal care differs in a number of ways and (2) that different kinds of neonatal care do influence both maternal and infant behaviour In the extra contact ($P+$) group mothers spent more time looking en face and kissing and their infants laughed or smiled more frequently In the control group (P) mothers spent more time cleaning their infants and these cried significantly more often The effects of the extra contact during the first hour after delivery were more pronounced for boys and their mothers than for girls and their mothers For example mothers in the extra contact group ($P+$) kissed and smiled at their boys more frequently and boys in the extra contact group ($P+$) smiled more often at their mothers than in the P group No such differences between $P+$ and P were found for girls and their mothers Differences in maternal and

infant behaviour between the two groups extra contact versus routine care were also found during an earlier observation at 36 hours after delivery (4)

Background factors concerning pregnancy delivery neonatal period (4) and the first 3 months at home (Table 6) were comparable in the two groups thus reinforcing the reality of the observed differences in behaviour The methodology in this field is so far incompletely explored Advantages and disadvantages of the methods used here were discussed in a previous paper (4) and it was concluded that reliable results can be obtained Using 61 observational items many of which could not appear simultaneously some chance differences in behaviour significant at the 5% level can be

somewhat more frequently at their boys ($p=0\ 07$) and other persons (father visitor) were slightly more often present during our observation ($p=0\ 08$) Boys with extra contact smiled significantly more frequently at their mothers ($p=0\ 03$) though no differences were found in alertness (eyes open, eyes closed)

Primiparous mothers with extra contact (P+) and without extra contact (P) compared by sex of infant Girls

Maternal behaviour (Table 4) differed significantly in only one respect mothers without extra contact cleaned (with a napkin or a piece of cleaning tissue) their girls more often ($p=0\ 02$) Girls in the extra contact groups had their eyes open during the entire period of observation whereas girls in the non contact group had their eyes closed ($p=0\ 08$) for some part of the observation period The *P* girls also cried slightly more frequently ($p=0\ 09$)

Primiparous mothers with (P+) and without extra contact (P)

A number of significant differences (Table 5) in maternal behaviour were found mothers in the extra contact group spent more time in looking en face ($p=0\ 008$) and kissing their infants ($p=0\ 009$) while they less frequently cleaned their infants ($p=0\ 05$) Holding the infant was equally frequent in both groups but mothers with extra contact more frequently cuddled their infants though this difference was not significant Infant crying was more frequently observed for non extra contact infants ($p=0\ 02$) and co variated with mother rocking more frequently the difference however did not reach a significant level Infant smiling and/or laughing appeared significantly more often in the extra contact infants ($p=0\ 02$)

B *The personal interview with the mothers*

The main results are shown in Table 6 The groups were comparable as regards planning of pregnancy and whether this was welcome or not the mother s perception of physical well being during the first 4 months and the second part of pregnancy participation in antenatal clinic programmes preparations for and perception of delivery husband s visiting patterns at maternity ward and mother s perception of first week at home The infants in both groups slept equally long at 3 months in both groups and an equal number had suffered from colic and received medication for it Although the mothers reported the same frequency of waking at night and infants in the extra contact group were given night feeds twice as long as infants in the control group mothers in the control group reported more problems with night feeding Mothers in the control group had help in the household during a longer period after discharge from the mater

nity ward and felt that adaptation to their infants was somewhat more difficult More mothers in the extra contact group were still breast feeding their infants at 3 months than in the control group (6) Further details of the personal interview with the mothers will be published later (5)

DISCUSSION

The present study has shown that 3 months after delivery (1) maternal behaviour with boys and girls within groups with the same type of immediate postnatal care differs in a number of ways and (2) that different kinds of neonatal care do influence both maternal and infant behaviour In the extra contact (*P*+) group mothers spent more time looking en face and kissing and their infants laughed or smiled more frequently In the control group (*P*) mothers spent more time cleaning their infants and these cried significantly more often The effects of the extra contact during the first hour after delivery were more pronounced for boys and their mothers than for girls and their mothers For example mothers in the extra contact group (*P*+) kissed and smiled at their boys more frequently and boys in the extra contact group (*P*+) smiled more often at their mothers than in the *P* group No such differences between *P*+ and *P* were found for girls and their mothers Differences in maternal and

infant behaviour between the two groups extra contact versus routine care were also found during an earlier observation at 36 hours after delivery (4)

Background factors concerning pregnancy delivery neonatal period (4) and the first 3 months at home (Table 6) were comparable in the two groups thus reinforcing the reality of the observed differences in behaviour The methodology in this field is so far incompletely explored Advantages and disadvantages of the methods used here were discussed in a previous paper (4) and it was concluded that reliable results can be obtained Using 61 observational items many of which could not appear simultaneously some chance differences in behaviour significant at the 5% level can be

expected The differences in maternal and infant behaviour in the present study are however more pronounced than can be expected by chance only

Klaus et al (8 9 15) have shown more systematically than others that neonatal care influences maternal behaviour both in the neonatal period and later on The present study extends their observations in three respects First it suggests that a naked 15–20 min extra contact was associated with changes in maternal behaviour similar to those accompanying the considerably longer extra contact used by Klaus et al i e one hour immediately after delivery and an additional 5 extra hours each afternoon during the next 3 days Secondly Klaus found differences between the treatment groups only when he lumped together several behavioural items as what he called maternal attachment behaviour' In this study we found differences in separate behavioural items In addition to maternal behaviours which can be involved in development of attachment such as kissing looking en face smiling and crying (3) we found differences also in other behaviour such as cleaning of infant and rocking Thirdly we found differences in infant behaviour which have not been studied by Klaus et al (8 9 15)

In our view many of the differences in behaviour observed have an emotional background and a value in the relationship between mother and infant Behaviour which can be expected to have a positive influence and value was found to occur more frequently in the extra contact group (*P*+) One of the marked differences in infant behaviour between the two groups concerned crying and smiling The former occurred more frequently in the routine care group the latter more frequently in the extra contact group Infant crying could be a sign of less well developed mother–infant synchrony It elicited cleaning and rocking more often in mothers in the control group Cleaning as well as rocking (2) may be interpreted as a kind of maternal soothing behaviour Such behaviour was more frequent in mothers with routine care and this could be the effect of more frequent infant crying in this group Infant smiling and laughing on the other hand was more frequent in the extra contact group possibly acting as a release mechanism eliciting instinctual responses in the mother (2) and serving as an activator of positive maternal behaviour mothers in the extra contact group more frequently showed such positive maternal behaviour i e kissing and regarding en face These findings receive support from Lewis (11) who during observation of mothers and 3 month old infants found a positive correlation between mother s smiling and infant s smiling We will not try to evaluate the impact of differing behaviour on later development only to mention that Bowlby (2 3) and Richards (14) agree that smiling plays a role in the growing mother–infant relationship

In studies on monkeys Mitchell (12) found that frequency and form of mother–infant contact depends on the behaviour of the mother and on the age and sex of infant In the present study we found differences in maternal and infant behaviour within groups with the same care depending on the infant s sex For example in the *P*+ group mothers with boys looked en face more frequently in the *P* group mothers cleaned girls more often Such sex differences might be acquired caused by difference in maternal attitudes associated with difference in their expectations of boys and girls Obviously they might also have a more biological background The fact that sex differences were already present at 36 hours (4) might speak in favour of a genetic cause or at least a prenatal moulding A most interesting and unexpected finding was that a change in care routine influenced boys and their mothers more than girls and their mothers For example infant smiling was seen more frequently in the *P*+ group both for girls and boys the influence being greatest on the boys however (Tables 3 and 4) Not only did infants behave differently in relation to sex but so also did mothers i e in kissing although whether this was due to acquired difference in attitude to

maternal responsivity (11) or to a biological mechanism for example differences in signals given by boys and girls must await further studies Moss (13) found differences in behaviour of mothers with boys and girls reared under similar circumstances The change in post partum care seems to reinforce this already pre existing difference between the two sexes

EFFECTS OF GROWTH HORMONE ON PROTEIN METABOLISM

Acute Changes in Plasma Amino Acids in Growth Retarded Patients with and without Growth Hormone Deficiency

NIKOLAUS STAHNKE CHRISTA PLETTNER and WERNER BLUNCK[1]

From the Department of Paediatrics University Hospital Hamburg Eppendorf University of Hamburg West Germany

ABSTRACT Stahnke N Plettner Ch and Blunck W (Department of Paediatrics University Hospital Hamburg and Children s Hospital Altona Hamburg West Germany) Effects of growth hormone on protein metabolism Acute changes in plasma amino acids in growth retarded patients with and without growth hormone deficiency Acta Paediatr Scand 66 153 1977.—39 patients with growth retardation were investigated 21 (group H) were suffering from GH deficiency and 18 (group N) had no endocrine disease except for two adequately treated patients with mild hypothyroidism Analysis of 15 plasma amino acid concentrations was carried out before and 1 and 2 hours after intravenous HGH *injection* at a dosage of 2 mg per m Except for one amino acid no significant difference between mean pre treatment amino acid values was observed in the two groups of patients In group H there was a highly significant decrease in plasma concentration of 14 amino acids already 1 hour after HGH injection and of all 15 amino acids after 2 hours This response of plasma amino acids to HGH was less pronounced in group N For 5 amino acids a moderate correlation was found in group H between acute metabolic response to HGH and growth response to long term HGH treatment Our results following HGH injection may reflect increased plasma amino acid transfer into cells due to HGH

KEY WORDS Growth hormone amino acids hypopituitarism dwarfism

Since Beck (2) 1957 initially recorded significant and consistent metabolic effects of human growth hormone (HGH) in man contradictory actions of HGH have been reported on protein metabolism Following several days of intramuscular HGH administration a marked decrease in blood urea and urinary nitrogen excretion was demonstrated by several studies (7 8 13 14 22 25 36 38) A significant increase in serum alpha amino nitrogen was found in hypopituitary patients after intramuscular HGH treatment for 5–6 days (25) and nearly all investigated amino acids showed an increase in plasma concentration due to 3–5 days of intramuscular HGH administration to hypopituitary dwarfs (40) Contrary to these findings other authors reported a decrease in plasma alpha amino nitrogen in GH-deficient dwarfs following an intravenous injection or infusion of HGH (10 27) In this context it appeared worthwhile to investigate plasma amino acid concentration in growth retarded patients with and without growth hormone deficiency before and after intravenous HGH administration

[1] Present address Children s Hospital Altona Hamburg West Germany

MATERIALS AND METHODS

39 patients with growth retardation were examined All patients were below the 3rd percentile for height To evaluate GH secretion plasma HGH was determined during insulin induced hypoglycemia and arginine infusion

Tyrosine	0 83±0 06 (18)	0 81±0 06 (14)	0 73±0 05 (17)	n s	<0 05
Phenylalanine	0 92±0 07 (17)	0 79±0 05 (14)	0 76±0 05 (16)	n s	<0 05

(20) Thyroid stimulating hormone function was evaluated by protein bound iodine (PBI) concentration and by thyroid uptake of [131]I ACTH function was evaluated by the 2-day metyrapone test (5) and an ACTH infusion test (37) In response to oral administration of metyrapone the excretion of 17-OH-corticosteroids was measured in urine (31) tetrahydrodesoxycortisol and tetrahydrocortisol being measured separately (5) Plasma corticosteroids were determined after intravenous infusion of corticotropin (4) As a rough screening test for adiuretin deficiency the specific gravity was repeatedly measured in the first urine portion in the morning

21 patients showed clinical and biochemical evidence of hypopituitarism (group H aged 6–21 years 18 males and 3 females) The mean maximum GH response to insulin induced hypoglycemia was 1 27 ng/ml±0 19 (S E M) and to arginine infusion 1 34 ng/ml±0 20 (S E M) 13 of these 21 patients were considered to suffer from isolated GH deficiency However the definite diagnosis of an isolated GH deficiency must await the appearance of puberty in these patients Onset of puberty was observed in 7 of these 13 patients whereas in the remaining 6 patients skeletal maturation was too much retarded to expect pubertal development All studies in this group of patients have been performed prior to HGH treatment

GH deficiency could be excluded in the remaining 18 patients with short stature (group N aged 5–17 years 14 males and 4 females) The mean maximum GH response to insulin induced hypoglycemia was 14 62 ng/ml±2 12 (S E M) and to arginine infusion was 13 04 ng/ml±2 41 (S E M) In two patients a mild hypothyroidism was found they had received adequate thyroid hormone replacement therapy for several months before our investigation started In the remaining 16 patients detailed physical and laboratory evaluation revealed no endocrine disease This group included 7 patients with constitutional delay in growth and sexual maturation 4 patients with familial short stature 4 patients with familial short stature combined with constitutional delay in growth and sexual maturation and 1 patient with Russell Silver syndrome

After an overnight fast patients were kept in bed and were permitted to drink only water At 8 a m they received HGH intravenously at a dosage of 2 mg/m² of body surface area HGH was commercially obtained and prepared by the method of Roos with a potency of 2 international units per mg (Crescormon Deutsche Kabi GmbH Munchen West Germany) Prior to and one and two hours after HGH injection blood was obtained for determination of concentration of 15 amino acids

GH was determined by double antibody radioimmunoassay (26) The lower limit of sensitivity of this assay in our laboratory is 0 5 ng/ml In our laboratory a peak plasma HGH concentration of at least 5 ng/ml is considered a normal GH response (34) Amino acid determinations were carried out by ion-exchange chromatography with a Beckman Unichrom amino acid autoanalyzer according to the procedure described by Spackman et al (33)

Statistical evaluation

Bartlett s test for homogeneity of variance and David s test for normality (ratio of range to standard deviation in the same normal sample) were performed prior to tests concerning the difference of two means According to these results nonparametric tests (the Mann Whitney U test for independent samples and the Wilcoxon sign rank test for correlated data) or the two tailed t test were carried out Group differences (group H and group N see above) in the metabolic response to HGH were compared by analyses of variance Additionally Spearman s coefficient of rank correlation (r) was calculated for the acute metabolic response to HGH injection and the growth response to long term HGH treatment (29) Since all results of amino acid analyses were not available in every patient sample size of data was different

RESULTS

Pre treatment amino acid concentrations in group H compared to those in group N

There was no significant difference between the mean pre treatment amino acid values in group H and group N except for one amino

Table 2 *Significant decrease in all 15 investigated amino acid concentrations in GH lacking patients*

acid. The mean pre-treatment concentration of leucine was significantly higher ($p<0.05$) in patients lacking GH than in patients without GH deficiency.

Changes in plasma concentrations of amino acids in group H and group N with HGH therapy

In patients without GH deficiency (group N) there was a significant decrease from the initial level in 8 out of 15 amino acid concentrations 2 hours after HGH injection. 4 of these 8 amino acids showed significantly reduced values already one hour after HGH injection (Table 1). In GH lacking patients (group H) there was a highly significant fall from the initial level in all of the 15 amino acid concentrations 2 hours after HGH injection; all amino acids except for one exhibited significantly decreased plasma concentrations already one hour after HGH administration (Table 2). Summarizing, patients with GH deficiency had a greater and more consistent decrease in amino acid concentration following HGH injection. The two groups of patients (group H and N) showed a significantly different response of 9 plasma amino acids to HGH administration (Table 3).

However, there was some overlap of individual values. Fig. 1 shows the percentage change in individual plasma concentrations of 1 amino acid (methionine) with the smallest overlap.

Relation between acute metabolic response to HGH and growth response to long term HGH treatment

Only for 5 amino acids a moderate correlation was observed in GH lacking patients between

(20) Thyroid stimulating hormone function was evaluated by protein bound iodine (PBI) concentration and by thyroid uptake of [131]I ACTH function was evaluated by the 2-day metyrapone test (5) and an ACTH infusion test (37) In response to oral administration of metyrapone the excretion of 17-OH-corticosteroids was measured in urine (31) tetrahydrodesoxycortisol and tetrahydrocortisol being measured separately (5) Plasma corticosteroids were determined after intravenous infusion of corticotropin (4) As a rough screening test for adiuretin deficiency the specific gravity was repeatedly measured in the first urine portion in the morning

21 patients showed clinical and biochemical evidence of hypopituitarism (group H aged 6–21 years 18 males and 3 females) The mean maximum GH response to insulin induced hypoglycemia was 1 27 ng/ml±0 19 (S E M) and to arginine infusion 1 34 ng/ml±0 20 (S E M) 13 of these 21 patients were considered to suffer from isolated GH deficiency However the definite diagnosis of an isolated GH deficiency must await the appearance of puberty in these patients Onset of puberty was observed in 7 of these 13 patients whereas in the remaining 6 patients skeletal maturation was too much retarded to expect pubertal development All studies in this group of patients have been performed prior to HGH treatment

GH deficiency could be excluded in the remaining 18 patients with short stature (group N aged 5–17 years 14 males and 4 females) The mean maximum GH response to insulin induced hypoglycemia was 14 62 ng/ml±2 12 (S E M) and to arginine infusion was 13 04 ng/ml±2 41 (S E M) In two patients a mild hypothyroidism was found they had received adequate thyroid hormone replacement therapy for several months before our investigation started In the remaining 16 patients detailed physical and laboratory evaluation revealed no endocrine disease This group included 7 patients with constitutional delay in growth and sexual maturation 4 patients with familial short stature 4 patients with familial short stature combined with constitutional delay in growth and sexual maturation and 1 patient with Russell Silver syndrome

After an overnight fast patients were kept in bed and were permitted to drink only water At 8 a m they received HGH intravenously at a dosage of 2 mg/m² of body surface area HGH was commercially obtained and prepared by the method of Roos with a potency of 2 international units per mg (Crescormon Deutsche Kabi GmbH Munchen West Germany) Prior to and one and two hours after HGH injection blood was obtained for determination of concentration of 15 amino acids

GH was determined by double antibody radioimmunoassay (26) The lower limit of sensitivity of this assay in our laboratory is 0 5 ng/ml In our laboratory a peak plasma HGH concentration of at least 5 ng/ml is considered a normal GH response (34) Amino acid determinations were carried out by ion-exchange chromatography with a Beckman Unichrom amino acid autoanalyzer according to the procedure described by Spackman et al (33)

Statistical evaluation

Bartlett s test for homogeneity of variance and David s test for normality (ratio of range to standard deviation in the same normal sample) were performed prior to tests concerning the difference of two means According to these results nonparametric tests (the Mann Whitney U test for independent samples and the Wilcoxon sign rank test for correlated data) or the two tailed t test were carried out Group differences (group H and group N see above) in the metabolic response to HGH were compared by analyses of variance Additionally Spearman s coefficient of rank correlation (r) was calculated for the acute metabolic response to HGH injection and the growth response to long term HGH treatment (29) Since all results of amino acid analyses were not available in every patient sample size of data was different

RESULTS

Pre treatment amino acid concentrations in group H compared to those in group N

There was no significant difference between the mean pre treatment amino acid values in group H and group N except for one amino

amino acid concentration should be expected (11 39) Two studies have shown that continued fasting does not lead to any consistent and appreciable change in blood amino acid concentration during a period of the same length as in our study (1 11)

Our findings of reduced plasma amino acid levels following HGH administration are probably not due to changed amino acid absorption or excretion since absorption and fecal excretion of nitrogen showed little or no response to HGH administration (22 36 38) No significant influence of GH on urinary excretion and clearance of amino acids was observed after 3–5 days of HGH therapy (40) at high dosage a renotropic effect could be demonstrated earliest on the 4th day (3) All these results however have been obtained in studies performed under conditions not completely comparable to ours

In rats lower serum and higher tissue levels of alpha amino isobutyric acid (AIB) were observed as early as 15–30 min after intraperitoneally GH injection (28) These findings suggest GH stimulation of plasma amino acid transport into tissues and could explain our results following intravenous GH treatment It is well known that GH increases in vitro and in vivo the rate of net transport of amino acids across cell membranes into the intracellular fluid of a variety of tissues (17 23 32 35) These effects have been shown to occur within 10–30 minutes following GH administration (15 17 28) An increase in protein biosynthesis in cells known to occur in response to GH is not only due to enhanced amino acid influx Above all GH directly exerts its protein anabolic action by stimulating ribosomal activity and synthesis of messenger and ribosomal RNA (12 16 35) Whether somatomedin plays an important role in mediating these effects of GH is still open to question (6 18 19) Whereas the reduction in plasma amino acid concentration one and two hours after intravenous injection of HGH most likely reflects increased transfer of plasma amino acids to intracellular compartments the observed increase in serum alpha amino nitrogen (25) and plasma amino acids (40) following several days of intramuscular HGH treatment could be due to stimulation of protein synthesis

Since a clear separation was not possible between patients with and without GH deficiency due to overlap of individual plasma amino acid levels the differential diagnostic value of this short term metabolic test is limited

Only for some amino acids a moderate correlation was observed in GH lacking patients between decrease in amino acid concentration one hour after HGH injection and growth velocity during 6 or 12 months of HGH treatment In a small group of patients the degree of GH induced nitrogen retention was related to the subsequent course of long term HGH therapy (22) In other studies however acute metabolic responses to HGH did not correlate well with height acceleration obtained on long term HGH treatment (8 13 38)

fall in amino acid concentration one hour after HGH injection and growth velocity during 6 months or 12 months of HGH therapy (Table 4)

DISCUSSION

In our study no significant difference was observed between mean pre treatment plasma amino acid concentrations in patients with and without GH deficiency with the exception of one amino acid Lower values for plasma amino acids in hypopituitary patients have been described (24 40) However in a subsequent study of one of the authors (41) two of these amino acids showed higher basal levels in GH lacking patients compared to normal controls Likewise other authors reported nonuniform results Serum alpha amino nitrogen levels were found to be in the same range in hypopituitary patients and in controls (25) In animals hypophysectomy did not change plasma concentration of some investigated amino acids (32), whereas in an other study a marked increase in serum level of alpha aminoisobutyric acid (AIB) was observed (28) For interpretation of all these results the normal circadian fluctuations of blood amino acid levels must be taken into account

In our patients HGH administration led to marked decrease in plasma amino acid concentrations one and especially two hours after HGH injection A much greater responsiveness to exogenous HGH was observed in our patients lacking endogenous GH than in patients without GH deficiency a fact which is well known (7 8 22, 25 36 38 41)

Our findings are in agreement with studies in animals and man A rapid fall in plasma amino acids free amino acid plasma nitrogen and plasma alpha aminoisobutyric acid (AIB) respectively was demonstrated in hypophysectomized animals following GH injection (9 21, 28) In man HGH infusion or intravenous injection cause a marked decrease in serum alpha amino nitrogen levels (10 27) A reduction of two plasma amino acids following intravenously administered HGH has been reported in patients with GH deficiency (41) A significant drop of 4 plasma amino acids after intravenous HGH injection in normal subjects has been described (30)

It is very unlikely that the observed decrease in plasma concentrations of amino acids in our study merely represents circadian fluctuation since for the time under study an increase rather than a decrease of plasma

ESTROGEN TREATMENT IN TALL GIRLS

N KUHN W BLUNCK N STAHNKE J WIEBEL and R P WILLIG

From the University Children s Hospital Hamburg and the Children s Hospital Altona Hamburg West Germany

ABSTRACT Kuhn N Blunck W Stahnke N Wiebel J and Willig R P (University Children s Hospital Hamburg West Germany) Estrogen treatment in tall girls Acta Paediatr Scand 66 161 1977.—36 tall girls aged 10.3 to 15 5 years were treated with ethinylestradiol (0 5 mg/day) and norethisterone (15 mg/day) To date treatment for seventeen girls has been completed Before treatment their bone age ranged from 11 0 to 13 5 years and mean height prediction was 185 19 cm (181 40–193 00 cm) After about two years of treatment their final height averaged 178 96 cm (171 60–183 50 cm) Predicted height was reduced by an average of 6 23 cm The reduction in final height was significantly greater when therapy was started before a bone age of 12 years Thirteen girls re-examined after discontinuation of therapy all had regular menstrual bleeding within six months There were no serious or irreversible side effects during the period of observation

KEY WORDS Tall girls estrogen therapy

Since excessive height may cause severe psycho-social problems there is some justification for limiting height in girls by estrogen therapy (11 12 18 23 28 35) Further deterioration of deformities of the spine in growing girls such as scoliosis or Scheuermann s disease can also be ameliorated by this treatment Goldzieher (12) in 1956 was the first to report on a premature halt in growth in girls induced by high doses of estrogens Since then many other reports on this treatment have been published (2 4 5 10 11 13 18 22 23 24 26 28 29 30 31 32 33 35) However there is still no unanimity on an optimal scheme of therapy Since 1971 we have been treating young girls with high doses of estrogens to prevent excessive height or for orthopaedic reasons The results and our general experience of this treatment are reported here

METHOD AND CLINICAL MATERIAL

35 healthy girls and one further girl with Marfan syndrome aged between 10 3 and 15 5 years were treated with high doses of estrogens to prevent excessive height Seven of these girls had their menarche before therapy was started Treatment of seventeen girls has been completed There was no significant difference with regard to chronological age bone age or height during the initial period of observation between these girls and the other nineteen still under treatment Therapy was started only if a final height of more than 185 cm was expected and if first signs of pubertal development were present to avoid the psychological stress of the sudden onset of pubertal development in a young girl (24 35) In a few cases severe psychological problems were the reason for beginning treatment although growth prognosis was less than stated above The growth prognosis was calculated according to the tables by Bayley & Pinneau (1) based on actual height and skeletal maturation as determined from the atlas of Greulich & Pyle (16) The parents and patients gave their written consent after being informed about treatment and its possible side effects The patients were examined at least every six months during treatment which was con

Table 1 *Over all results for patients with completed treatment (n=17)*

S D	1 17	0 62	3 02	0 74	3 14	3 29	2 82

tinued until the skeletal age was 15 years or more At first we used mestranol in a few cases but subsequently ethinylestradiol (Lynoral® Progynon M® 0 5 mg/day) for the first 25 days of each cycle and norethisterone (Primolut N® 15 mg/day) for days 21 to 25 were given This was followed by five days without treatment (days 26–30) 13 girls had follow up examinations for 1 5 years after therapy had been stopped

Statistical evaluation was based on the nonparametric Mann Whitney *u* test (7)

RESULTS

Treatment of seventeen girls has been completed At the beginning their mean chronological age was 12 7 years their mean bone age was 12 58 years and their mean height 175 08 cm Their mean predicted height was 185 19 cm After about two years of treatment their mean height was 178 96 cm 6 23 cm less than the predicted height Data (mean range and standards deviation) are presented in Table 1

Where therapy was started before a bone age of 12 years 8 92 cm were saved as compared to 5 49 cm when therapy was started with a bone age between 12 and 13 years This difference is statistically significant ($p<0.02$) In one girl with a bone age of 13 5 years growth prognosis could be reduced by only 1 cm (Table 2)

There was no significant difference in the height finally achieved whether the start of therapy came before or after menarche In the former case 6 43 cm were saved in the latter 5 76 cm (Table 3)

During the first phase of estrogen therapy skeletal maturation advanced more rapidly than the chronological age Later both advanced at the same speed (Fig 1) Growth velocity was reduced to about 3 cm/year during the first six months of therapy to about 2 cm/year during the second six months of therapy and in the following period to about

Max	16 16	13 50	177 70	2 80	181 00	184 40	10 40
S D	0 43	0 47	2 91	0 72	3 41	1 07	3 66

1 cm/year Growth after discontinuation of therapy was about 1 2 cm (range 0 4–2 8 cm) The decrease of growth velocity and prognosis is illustrated in the two curves in Fig 2

To date 13 girls have been re examined after discontinuation of therapy All had regular menstrual bleeding within six months In seven girls basal body temperature was reliably measured for some months None had proven ovulatory cycles and some had a cycle with an insufficient corpus luteum period

Side effects of therapy

There were no serious or irreversible side effects of estrogen therapy during the period of observation Almost all the girls had an increase in body weight averaging 11 1 kg but most did not become overweight as they were underweight before therapy After therapy weight loss averaged 6 5 kg Related to chronological age body weight was on the 90th percentile at the beginning and between 90th and 97th percentile after therapy whereas height was above 97th percentile

During the first 2–3 days of therapy most of the girls had nausea and some vomited An increase of pigmentation of areola and nipples of the breast developed in many but normalized after discontinuation of therapy In 5 out of 36 girls galactorrhea was observed for a few days but disappeared spontaneously during unaltered therapy In 3 girls a pre existent small goiter became bigger but decreased in size after substitution with thyroid hormone Acne vulgaris consistently vanished during estrogen therapy but reappeared after discontinuation in some girls In one girl therapy was stopped because of severe headache which immediately disappeared

DISCUSSION

Since the first report by Goldzieher (12) many other studies on estrogen treatment for tall

of Tanner & Whitehouse (27) Taking this in to account our mean growth reduction of 6 23 cm is well in line with his results

Acceleration of skeletal development during therapy has commonly been found to be between 1 4 and 2 8 years/year (2 18 31 35) In our patients it was 1 6 years/year during the first year of treatment At the same time growth velocity is reduced (18 24 35) presumably due to reduced secretion of somatomedin during estrogen therapy (5 34)

The effect of different estrogen doses on growth are listed in Table 4 Synthetic estrogens in amounts smaller than those used by us also resulted in a significant reduction in final height (35) Observations on girls with scoliosis (20 21) cannot be compared because deformities of the spine interfere with estimation of final height

Serious side effects of estrogen therapy have not been observed so far In particular no sterility due to high estrogen doses interfering with the hypothalamic–pituitary–ovarian axis has not been documented and there are reports of successful pregnancies in women who had previously been treated for excessive height (8 10 28) Like others (13 18 26 28 35) we regularly saw the reappearance of normal menstrual bleeding once therapy had been stopped Since at this age ovulatory cycles are observed in only 10–16% of all girls (9) the finding of anovulatory cycles in our seven patients was not unexpected

We consider estrogen therapy to be justified in patients who are likely to be excessively tall For girls already taller than 160 cm at the age of ten years a first growth prognosis

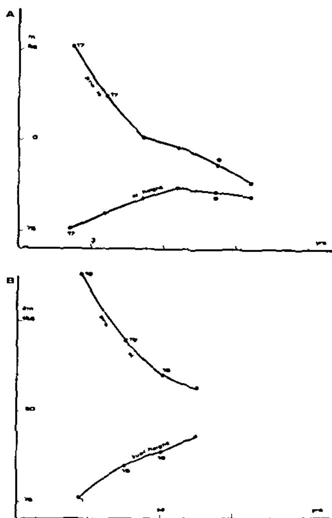

Fig ? Changes of predicted height with longitudinal growth *during estrogen therapy for patients with com* pleted therapy (A) and patients still under treatment (B) The decline in actual height in (A) between 14 and 15 years is due to the decreasing number of patients in the re spective subgroups (numbers indicate observations for each point on the figure)

stature in girls have been published (2 4 5 10 11 12 13 18 22 23 24 26 28 29 30 31 32 33 35) but there are still open questions especially with regard to possible late side ef fects *We therefore only started treatment in* girls with a growth prognosis of 185 cm or more although a lower limit has been chosen in Southern Germany and Switzerland (*5 24 35*) *where average adult height is less than in* Northern Europe (6) For girls with ortho paedic complications growth prognosis was not taken into account since further longi *tudinal growth had not been reduced*

The significance of results depends on the accuracy of height prediction *In accordance* with Zachmann (35) our impression is that future height is slightly overestimated using *the method of Bayley & Pinneau (1) but others (10 26 28) have found close agreement* between estimated and final height A longi tudinal growth study at the Fels Research Institute (Yellow Springs) and the Harvard *School of Public Health (Boston) on girls aged* between 10 and 14 years showed an under estimate of final height when the Bayley and Pinneau method was used but good agree ment was found at the Child Research Council (Denver) (25) The height predictions based on Tanner and Whitehouse II RUS (27) bone age estimations proved to be more accurate than *those calculated* according to Bayley & Pin neau (35) Another point is the accuracy in de termining bone age Since this can be difficult for the period shortly before or during the *adolescent growth spurt we took two or more X ray films of the wrist during the year before* therapy whenever possible to have more than one prediction of final height as a basis for the *decision on whether or not to treat*

Some of the results of estrogen therapy in young girls reported in the literature are listed in Table 4 and compare favourably with our observations There is no certain difference between the effects of cyclic or continuous estrogen treatment of final height We pref erred cyclic therapy to avoid possible hyper trophy of the endometrium *(3) and like others* we added norethisterone Since there is a pos sible connection between vaginal carcinoma in young women whose mothers had been treated with stilbestrol during pregnancy (14 *15 17 19) this estrogen is no longer recom* mended

In general reduction of final height has been more *successful when estrogen therapy has* been started before a skeletal age of 12 5 years (13 18 26 28 35) Starting therapy before or after menarche did not alter our results and this has been observed by others (28 35) Zachmann (35) found a mean growth reduc tion of 4 26 cm using *the prediction method*

Table 4 *Comparison of our results with those in the literature*

LEAD IN UMBILICAL CORD BLOOD CORRELATED WITH THE BLOOD LEAD OF THE MOTHER IN AREAS WITH LOW MEDIUM OR HIGH ATMOSPHERIC POLLUTION

B ZETTERLUND J WINBERG G LUNDGREN and G JOHANSSON

From the Departments of Paediatrics and Analytical Chemistry University of Umeå Sweden

ABSTRACT Zetterlund B Winberg J Lundgren G & Johansson C (Departments of Paediatrics and Analytical Chemistry University of Umeå Sweden) Lead in umbilical cord blood correlated with the blood lead of the mother in areas with low medium or high atmospheric pollution Acta Paediatr Scand 66 169 1977.— Lead concentrations in 541 samples of umbilical cord blood from different parts of Sweden were determined The mean concentration was 7 6 μg lead/100 ml (=0 367 μmol/l) The blood lead values were also determined for 297 mothers and a mean value of 8 7 μg/100 ml (=0 420 μmol/l) was found There was a significant correlation between the blood lead level of the mother and the infant as studied in 253 pairs The slope of the regression line was 0 5 r (r=0 6) Significantly lower blood values for both mother and infant were found in areas with low pollution as estimated from the lead content in moss No seasonal variation could be ascertained Hematocrit versus lead concentration was also studied A flameless atomic absorption method was used with a standard deviation of 0 9 μg lead/100 ml The storage time and sample treatment were also studied

KEY WORDS Lead newborn infants maternal–fetal exchange environmental pollutants

The environmental health risks from exposure to metals or metal compounds have been a matter for serious concern during recent years (31) The childhood exposure to environmental lead has been studied by Darrow et al (8) who also reviewed other works Sayre et al (26) studied dust as a source for childhood exposure There has however been little attention given to the exposure of fetuses or infants and very few data are available as pointed out by Scanlon (27) The metal intake in early life should therefore be investigated as it is expected that the effect of metals is larger on rapidly growing tissue than on that of the adult individual (5 18) Lead intoxication in utero is wellknown and there are many reports in the literature (32) Other studies have indicated a placental transfer of lead in absence of obvious intoxication symptoms of mother or infant (11 12 15 17 23 24 28)

Significant differences between urban and suburban infants or infants with smoking and nonsmoking mothers have not been demonstrated in these studies

The number of patients studied have often been small and the accuracy and sensitivity of the analytical methods used have not always been appropriate since they have been developed mainly for patients with professional lead exposure The blood levels to be expected in newborns are much lower than those found in professionally exposed workers The method to be selected should therefore have a detection limit of at least 1 μg/100 ml blood Several methods have been used for the determination of lead in blood e g spectrographic

Table 3 *Effect of storage time on the blood lead value (µg lead/100 ml)*

Analytical methods

Lead was analyzed by flameless atomic absorption spectroscopy using instrumentation which has been described earlier (19 20) as well as on a Varian AA6 with a CRA 63 graphite furnace On analysis with our own graphite furnace the blood was diluted to ten times its original volume with water using a pneumatic dilutor To 1 0 ml of diluted blood 50 µl of 2% Triton X 100 was added to ensure total haemolysis of the red blood cells A small aliquot (1–5 µl) of the sample was placed in the graphite tube atomizer with a micropipette (Unimetric or Oxford sampler) The working parameters for a lead determination were drying for 30 sec at 100°C ashing for 30 sec at 650°C and atomization at 1 300°C

The procedure used with the CRA 63 was identical except that the sample was diluted to three times its original volume with 2% Triton X 100 The difference in procedure is due to different sensitivity and differences in the formation of particles with non specific absorption

A calibration curve was obtained from standard additions of small volumes of lead nitrate stock solution The reproducibility at low levels is shown in Table 2 the standard deviation of the analytical method was 0 9 µg lead/100 ml 22 blood samples from workers at a lead melting plant (Boliden AB Sweden) were analyzed and compared with the results obtained by their analytical department using an extraction method (34) The largest difference was 2 µg/100 ml at a level of 10–48 µg/100 ml (1 µg/100 ml=0 048 µmol/l) The delay before analysis should be of little importance for the result as shown by Table 3 If the samples were partially coagulated the results were different even on the same day and in order to obtain reliable values such samples must be discarded without hesitation Attempts to dissolve such samples in acids were not successful

Hematocrit was estimated by centrifugation of microtubes at 11 000 RPM for 4–5 min

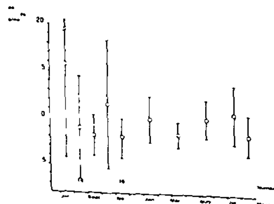

Fig 1 Seasonal variations of lead concentrations in maternal blood Umeå 1973–1974 Mean values±1 S D 1?7 samples 1 µg/100 ml=0 048 µmol/l

RESULTS

In four maternal blood samples out of 297 (1 3%) and in eight out of 541 cord blood specimens (1 5%) the lead concentration was above 20 µg/100 ml blood The mean concentration was 8 7 µg/100 ml (=0 420 µmol/l) for the mothers and 7 6 µg/100 (=0 367 µmol/l) for the fetuses Seasonal variations of maternal and fetal lead levels in the samples from Umeå are shown in Figs 1 and 2 No definite conclusions can be drawn from the results The high mean levels found in July 1973 for both mothers and infants are based on eight samples Since these first eight determinations belonged to the 15 highest values found in the

(7) atomic absorption spectrometry after extraction with APCD in MIBK (14 34) and spectrophotometry using dithizone An adequate sample treatment has been one of the main difficulties Treatment with heparin and triton has been applied but still the analysis presents several pitfalls as illustrated by a recent review (2) as well as a comparison between different techniques (1) It has been shown that flameless atomic absorption in a graphite tube can provide reliable results provided a background correction is used in a two channel instrument (19–21) The background correction subtracts non selective absorption due to smoke or particles The temperature must be controlled during the ashing step in order to perform the ashing at a temperature just below that at which losses occur In this way the non specific absorption is reduced and accuracy is improved Difficulties with the formation of ash on the graphite surface still remain (10)

The present study was planned so that samples would be obtained from areas with various atmospheric lead levels including urban as well as suburban regions The relation between maternal and fetus blood levels was also studied Sources other than atmospheric lead pollution may be more important but data for comparisons were not available The present material was not examined for clinical symptoms since no such effects were expected at the lead levels found The results are presented in µg/100 ml blood 1 µg/100 ml= 0 048 µmol/l

MATERIAL

Blood samples were collected in Umeå from July 1973 until August 1974 and in other places in Sweden from October 1973 until November 1974 541 cord blood samples and 297 samples from delivered mothers were analyzed Blood samples were obtained from the maternity clinics in the cities listed in Table 1 The patients (age 16–43 years mean 25 6 years) lived in the corresponding cities or in the surrounding region These places were chosen because they represented regions with low intermediate and high atmospheric pollution of lead according to Tyler & Ruhling (25) cf Table 1 The pollution was estimated from the lead content of a moss (*Hylocomium splendens*) which reflects the pollution during the 5–6 years preceding collection (30) The moss was collected (1968–1969) at places situated at least 300 m from a road Lead from motor car fuel was judged not to have influenced the values

METHODS

Blood sampling

Maternal venous blood was collected just after delivery into heparinized test tubes (Vacutainer L 320 XF 313) Cord blood was allowed to flow directly into the test tube The specimens were kept at +4 C until analysis was performed During transportation temperature was not checked The most critical operation was found to be the shaking of the Vacutainer tubes just after the sampling If not properly performed the blood would coagulate during transport

Test tubes stoppers and canulas did not yield measurable quantities of lead when washed in HNO_3 for 24 hours The heparin was free from lead

Table 2 *Variation in samples with low levels of lead (cord blood)*

1131	4 2	5 6	5 3	4 9	5 0

sis separately for each geographical region No variation was found The possibility that the quotient may differ at different maternal lead levels was also tested and rejected The age of the mother did not influence the lead level of her blood or that of her infant

As it is supposed (6 24) that more than 95% of the lead in the blood is bound to the red cells the values of the infants were correlated with the hematocrit see Fig 4 A correlation coefficient of 0 19 was obtained and therefore the variations seen in cord blood/maternal blood quotient cannot be explained in this way In an examination of blood from 16 mothers no correlation was found between lead value and hematocrit (r=0 08) These results are supported by Kochen & Greener (15) who stated that hematocrit is of little importance for lead uptake in blood when lead levels are below 250 µg/100 ml (=12 µmol/l)

DISCUSSION

The mechanism for transfer of lead from mother to infant is unknown In two studies (11 12) a slightly higher concentration has been found in maternal blood than in fetal cord blood No conclusions about the transport mechanism can be drawn from these data or from the autopsy material published by Schroeder & Tipton (29)

Studies on rat fetuses after a single injection

Estimated from the figure

of lead 203 (16) cannot imitate the long low dose exposure of the ordinary pregnant woman

This study has shown that in the majority of 297 maternal and 541 cord blood samples the lead concentration was between 5 and 15 µg/100 ml blood (0 241–0 724 µmol/l) The values were lower in areas with low atmospheric pollution There are few reports in the literature on cord blood lead levels Table 5 summarizes some published data The present Swedish data especially those from the northern part of the country seem to be much lower than the American and German ones If the difference is real or due to methodological discrepancies is uncertain

Estimates of the natural lead concentration in organic materials have suggested a natural human blood concentration of 0 025 µg/100 ml (0 001 µmol/l) (22) Compared with this the present values are high Biochemical effects of low lead concentrations have been demonstrated by Hernberg & Nikkanen (13) who found a decreased activity of deltaaminolevulinic acid dehydratase in erythrocytes at blood lead values between 5 and 15 µg/100 ml

A crucial question is however whether the blood lead levels found in the present and in other studies may be clinically harmful in the long run Little is known about risks of long term exposure to low levels this applies especially to fetuses and infants Encephalopathy in children is seen after acute lead intoxication but a few studies suggesting cerebral symp

37 samples from a big city (Stockholm) gave a mean of 9 4 μg Pb/100 ml blood for the mothers and 6 8 μg Pb/100 ml for the cord blood

whole study (838) samples) an error cannot be excluded

Geographical variations in lead levels were then analyzed Table 4 compares the lead content of maternal and of cord blood for geographical regions with different grades of atmospheric pollutions The lowest mean value was obtained from the northern part of the country (area A) where pollution is low The difference was highly significant ($p<0\ 001$) for both mothers and infants in comparison with regions with intermediate (B) and high (C) pollution In the latter areas maternal levels did not differ significantly Unexpectedly the blood lead concentrations were lower in the highly polluted region C than in region B ($p<0\ 05$ for cord blood) To see whether this could be explained by the fact that part of the population in area B lived in a big city (Stockholm) the mean values for these individuals were calculated separately see Table 4

The lead concentration of the maternal blood was then plotted versus that of the fetal blood for 253 mother and infant pairs see Fig 3 The slope of the regression line was 0 53 ($r=0\ 62$) the fetal level being lower than the maternal one A large number of values fall far from the regression line This indicates that factors other than the actual blood concentration of the mother influence the cord blood level The correlation between fetal and maternal blood was submitted to statistical analy

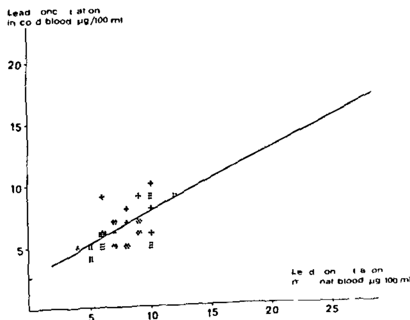

Fig 3 Correlation between maternal and fetal blood lead concentrations for 253 mother–infant pairs Correlation coefficient =0 62 1 μg/100 ml=0 048 μmol/l

sis separately for each geographical region No variation was found The possibility that the quotient may differ at different maternal lead levels was also tested and rejected The age of the mother did not influence the lead level of her blood or that of her infant

As it is supposed (6 24) that more than 95% of the lead in the blood is bound to the red cells the values of the infants were correlated with the hematocrit see Fig 4 A correlation coefficient of 0 19 was obtained and therefore the variations seen in cord blood/maternal blood quotient cannot be explained in this way In an examination of blood from 16 mothers no correlation was found between lead value and hematocrit ($r=0\ 08$) These results are supported by Kochen & Greener (15) who stated that hematocrit is of little importance for lead uptake in blood when lead levels are below 250 µg/100 ml (~12 µmol/l)

DISCUSSION

The mechanism for transfer of lead from mother to infant is unknown In two studies (11 12) a slightly higher concentration has been found in maternal blood than in fetal cord blood No conclusions about the transport mechanism can be drawn from these data or from the autopsy material published by Schroeder & Tipton (29)

Estimated from the figure

of lead 203 (16) cannot imitate the long low dose exposure of the ordinary pregnant woman

This study has shown that in the majority of 297 maternal and 541 cord blood samples the lead concentration was between 5 and 15 µg/100 ml blood (0 241–0 724 µmol/l) The values were lower in areas with low atmospheric pollution There are few reports in the literature on cord blood lead levels Table 5 summarizes some published data The present Swedish data especially those from the northern part of the country seem to be much lower than the American and German ones If the difference is real or due to methodological discrepancies is uncertain

Estimates of the natural lead concentration in organic materials have suggested a natural human blood concentration of 0 025 µg/100 ml (0 001 µmol/l) (22) Compared with this the present values are high Biochemical effects of low lead concentrations have been demonstrated by Hernberg & Nikkanen (13) who found a decreased activity of deltaaminolevulinic acid dehydratase in erythrocytes at blood lead values between 5 and 15 µg/100 ml

A crucial question is however whether the blood lead levels found in the present and in other studies may be clinically harmful in the long run Little is known about risks of long term exposure to low levels this applies especially to fetuses and infants Encephalopathy in children is seen after acute lead intoxication but a few studies suggesting cerebral symp

toms after sublinical lead exposures are also published David et al (9) reported slightly higher blood lead values in a group of hyper active children compared with controls but there is no proof of a causal relation between the hyperactivity and lead Another report (3) suggests correlation between mental retardation and lead content in drinking water in Glas gow In both of these investigations the con trols had blood lead levels of 17 and 23 μg/100 ml and the affected children 24 and 26 μg/100 ml In a follow up study de la Burde et al (4) found impaired cognitive perceptual and behavioural functioning in a group of children 4–6 years after proved lead exposure without acute symptoms The observed group had blood lead levels exceeding 40 μg/100 ml at the exposure

Although the levels reported here are lower than those reported from several other coun tries there is still reason for concern about the increasing lead exposure (33) especially for fetuses and small children It thus seems war ranted to follow the impact of this regularly for example by (*a*) surveying lead concentra tions and sources of lead exposure (*b*) to look for possible clinical effects especially long term consequences and (*c*) to learn more about transport and biochemical effects of lead and lead compounds in the body

ACKNOWLEDGEMENTS

We thank the staff of obstetric and paediatric depart ments who were most helpful in collecting the blood samples Dr Ivar Holmqvist for much valuable advice and continued interest in this investigation Miss Margaret Tullberg for technical assistance We also thank Dr Mi chael Sharp for linguistic revision of the manuscript This work was supported by a research grant from National Environmental Protection Board and the Expressen Foun dation for Prenatal Research

C PEPTIDE IN JUVENILE DIABETICS BEYOND THE POSTINITIAL REMISSION PERIOD

Relation to Clinical Manifestations at Onset of Diabetes Remission and Diabetic Control

J LUDVIGSSON L G HEDING[2] Y LARSSON[1] and E LEANDER[3]

From the Department of Paediatrics Linkoping University Sweden [1]Novo Research Institute Copenhagen Denmark and the [3]Department of Mathematics Linkoping University Sweden

ABSTRACT Ludvigsson J Heding L G Larsson Y and Leander E (Department of Paediatrics Linkoping University Sweden Novo Research Institute Copenhagen Denmark Department of Mathematics Linkoping University Sweden) C peptide in juvenile diabetics beyond the postinitial remission period —Relation to clinical manifestations at onset of diabetes remission and diabetic control Acta Paediatr Scand 66 177 1977 —A group of 58 diabetics age 6–17 years and with a duration of diabetes of 3–14 years was studied in order to show whether the nature of the clinical manifestations and the treatment at the onset of the disease are related to the subsequent C peptide production and also whether remaining C peptide production is related to better diabetic control The relations between a number of clinical and laboratory variables were analysed including the degree of ketosis and the insulin dose given at onset of diabetes the incidence of postinitial remission period the fasting C peptide level after the remission period the level of insulin antibodies and the actual diabetic control expressed as the degree of glucosuria in the patients urine tests at home Multiple regression analysis was the main method used Postinitial remission was positively correlated to initial insulin dose and negatively correlated to duration of ketonuria at onset C peptide which was found in 24 1% of the patients was positively correlated to age at onset and initial insulin dose but negatively correlated to ketonuria at onset Diabetic control was positively correlated to insulin dose at onset and to C peptide level but negatively correlated to insulin antibodies It could further be shown that patients who had received a more vigorous treatment immediately at onset had both a higher incidence of postinitial remission and a better diabetic control The results suggest that an early diagnosis followed by rapid normalization of the metabolism at the onset of juvenile diabetes increase the possibility of preservation of some of the endogenous insulin production which seems to facilitate diabetic control

KEY WORDS Juvenile diabetes ketonuria insulin remission C peptide insulin antibodies

C peptide is considered to reflect the insulin production of the beta cells (2 14 16 22) In juvenile insulin requiring diabetics C peptide levels equal to those present in non diabetics have been demonstrated in the postinitial remission period (1 3 9 13) Thereafter such patients are considered to have more or less completely lost their capacity for endogenous insulin secretion (7 21) However we were recently able to show that in a group of 96 diabetic children with more than two years of duration measurable amounts of C peptide were present in 35 4% of the patients (19) This indicates that a residual beta cell function may exist even for prolonged periods in some cases of juvenile diabetes It seemed to be of interest to study in more detail such cases and particularly to analyse whether the nature of

Table 3 *Duration of ketonuria at onset of diabetes*

Onset	Days 0	1–3	4–6	7–9	>9	Mean days	S D	Total *no*
Before Jan 1st 1970	4	8	8	7	12	6 9	5.5	39
After Jan 1st 1970	4	9	5		1	2 9	3 3	19
Total	8	17	13	7	13	5 7	5 2	58
%	13 8	29 3	22 4	12 1	22 4			100 0

METHODS

Clinical data were taken from patient records supplemented by questionnaires regarding heredity The degree of diabetic control was determined on the basis of the urinalysis made at home From the patients diaries during 1975 the number of tests showing less than 1% glucosuria was counted and expressed in percentage of all tests performed This figure was taken as an index of diabetic control Consequently a high index figure indicates a more normal glucose metabolism than a low figure

Postinitial remission was defined as the period following the first weeks of hospital treatment in which more than 95% of the urine tests at home and at the hospital showed less than 1% glucosuria for more than one week During this period the insulin requirements were low with a mean of 0 5 and a range of 0 0–0 9 IU/kg body weight For comparison the corresponding figures for 1975 were mean 1 1 and range 0 6–1 8 IU/kg body weight

Laboratory methods Blood was drawn from the fasting patients prior to their morning insulin injection Serum used for determination of C peptide IgG and IRI was stored at −18 C

C peptide was determined by a radioimmunoassay in which proinsulin is being removed through binding to insulin antibodies covalently coupled to Sepharose (12) Since most of the serum contained insulin antibodies which have been shown to bind proinsulin the serum was extracted at a low pH in the same way as described for total IRI (11) before the determination of C peptide Detection limit is 0 03 *pmol/ml* All serum samples were assayed in triplicates using antisera M1181 (12)

The insulin binding capacity of IgG was determined by the method of Christiansen (5) and total immunoreactive insulin IRI was determined after acid extraction of serum according to Heding (11)

HLA typing was performed by the lymphocytotoxic microtechnique described by Kissmeyer Nielsen and Kjerbye (15) Lymphocytes were isolated according to Thorsby (24) and Bøyum (4)

Statistical methods Multiple regression analysis was the main technique employed The following variables were included in the evaluation family history of juvenile diabetes mellitus family history of maturity onset diabetes mellitus HLA type (B8 and/or BW 15) sex age at onset of diabetes (age at onset of diabetes)² onset of diabetes before January 1st 1970 duration of diabetes (duration of diabetes)² infection before onset of diabetes blood glucose levels on first admission to hospital occurrence of severe ketoacidosis on first admission to hospital ketonuria on first admission to hospital duration of ketonuria at onset insulin dose during the first 24 hours at hospital (IU/kg body weight) occurrence of remission period square root of fasting serum C peptide index of diabetic control (during 1975) insulin binding capacity of IgG and total serum insulin IRI

RESULTS

Manifestations at onset Infections had according to available information preceded the onset of diabetes by at most two months in 16 patients (27 6%) In 4 asymptomatic patients (6 9%) the disease was diagnosed by chance at routine medical examination while the remaining 54 patients (93 1%) had had diabetic symptoms for an average of 20 days (range 2–120) before admission to hospital Nine patients (15 5%) were admitted to hospital with severe

the clinical manifestations and the treatment at the onset of the disease are related to the subsequent C peptide production and also whether remaining C peptide production is related to better diabetic control

MATERIAL

A sample of 58 insulin treated juvenile diabetics 6–17 years of age was studied All cases had passed the post initial remission period and the duration of diabetes varied from 3–14 years (mean 7 3±3 0) Age at onset of diabetes varied between 1–13 years (mean 6 0±3 4) Family history for diabetes is shown in Table 1 All patients were regularly seen at the diabetic clinic of the pediatric department 4–8 times a year In the statistical evaluation the patients were divided into two groups 39 patients with onset of diabetes before January 1st 1970 and 19 patients with onset thereafter This division of the material was done because in 1970 there was a change in the therapeutic policy both with regard to the initial treatment at onset and the following diabetic care Before 1970 diabetic patients at onset were given rather small gradually increasing doses of insulin correlated to laboratory data and severity of symptoms of the patient on admission to hospital (Table 2) Relatively prolonged periods of ketonuria were rather common (Table 3) Ketonuria was considered to be present until the urine was continuously negative for two days The aims of the subsequent treatment may be briefly described as clinical well being freedom from symptoms of diabetes and normal growth and development while less attention was paid to the metabolic control Urinalysis at home was not recommended and the diet was only roughly regulated After 1970 the treatment became more intense At onset higher insulin doses were given (Table 2) aiming at a normalization of blood glucose and elimination of ketonuria within 24–28 hours Thereafter the aim was a metabolic state as normal as possible This was achieved through a treatment consisting of insulin regular physical activity regulated diet (with the help of a dietitian) and daily glucosuria control at home Thus after 1970 all patients were instructed to test their urine three times a day usually before breakfast before dinner and in the evening by the Clinitest 2-drops method and to record the results in a diary shown to the doctor at each hospital visit They were also instructed to check their urine for ketone bodies with Ketostix in acute situations By the time of this study 28 patients (48 3%) tested their urine 2–3 times a day 29 patients (50 0%) 1–2 times a day and only one of the 58 patients (1 7%) did not test the urine regularly During both periods the patients were as a rule given one morning dose of intermediate insulin (NPH or Lente) often supplemented by shortacting insulin (Semilente® Actrapid® or Regular insulin) during the first years of diabetes but when this failed to keep them well regulated (usually coinciding with the first signs of puberty) two daily doses were given At the time for C peptide determinations 35 patients (60 3%) had two doses a day Growth and development (somatic psychological and intellectual) was within normal limits in all cases except in one boy with delayed onset of puberty

symptoms of ketoacidosis including drowsiness but nobody was unconscious On admission ketonuria was present in 50 patients (86 2%) (Table 3) Blood glucose levels on admission to hospital varied between 4 2–66 7 mmol/l (mean 23 5) Insulin doses given during the first 24 hours at hospital are shown in Table 2

Postinitial remission according to the definition used was more common and longer in boys than in girls (Table 4) In 7 patients the remission period exceeded two months

Diabetic control expressed as the glucosuria level in home testing during 1975 could be assessed in the 57 patients who tested their urine regularly In the majority of cases more than 50% of the test showed less than 1% glucosuria (Table 5)

C peptide was measurable (≥0 04 pmol/ml) in 14 patients (24 1%) In comparison with non diabetic children comparable with regard to age weight and sex (18) 5 had values within and 9 below the normal range (0 22–0 73 pmol/ml) In the remaining 44 patients (75 9%) no C peptide could be demonstrated

Insulin antibodies The mean value for IgG was 3 359±2 758 mU/ml (range 0 130–11 029) and for IRI 1 329±1 824 μU/ml (range 10–7 808) The correlation between the two methods was good (r=0 72 p<0 001)

HLA HLA B8 was present in 17 patients (29 3%) and BW15 in 18 patients (31 0%) The combination HLA B8W15 was seen in 4 patients (6 9%) Further details regarding HLA types in this material will be published elsewhere (20)

Partial correlations In the multiple regression analysis special attention was paid to the interdependence of the variables in patients with onset before 1970 and these results are given in detail in Tables 6–9 The tables do not include statistically significant correlations only but also others of importance in the regression analysis From the analysis of patients with onset after January 1st 1970 only statistically significant results are reported as non significant results in this smaller group of patients neither contradict nor confirm results already presented regarding the larger group of patients with onset before 1970

Remission Before 1970 remission periods occurred significantly more often in those patients who had received a relatively higher insulin dose during the first 24 hours at hospital at onset (p>0 02) (Table 6) When patients with onset after 1970 were added this relationship became even more pronounced (r=0 49 p<0 001) and a prolonged period of ketonuria at onset was significantly correlated to an absence of remission period (r=0 39 p<0 005) In addition with all other analysed variables kept constant patients with onset after 1970 had a higher incidence of remission periods (r=0 33 p<0 02)

C peptide The relations between C peptide and other variables are shown in Table 7 The level of C peptide was higher in patients with late onset of diabetes (p<0 001) but the cor

Insulin dose (IU/kg b wt) during the first 4 hours	2 87	0 48	<0 01	3 76	0 63	<0 001
Occurrence of remission	−2 71	−0 46	<0 02	–	–	–

relation to duration of diabetes was weak Prolonged ketonuria at onset was related to low levels of C peptide ($p<0\ 05$) while high insulin doses during the first 24 hours at onset were significantly related to high levels of C peptide ($p<0\ 01$) In the patients with onset before 1970 the occurrence of remission periods was negatively correlated to later C peptide level ($p<0\ 02$) but this relation was not found in patients with onset after 1970 Otherwise there were no significant differences in the pattern of relationships between patients with onset before and those with onset after 1970

Diabetic control The relation between the index of diabetic control in 1975 and some of the clinical and laboratory variables are shown in Table 8 Significant correlations were found with regard to duration insulin dose at onset and insulin antibodies When patients with onset after 1970 were added a high index was positively correlated to the amount of C peptide ($r=0\ 30$ $p<0\ 05$) and patients with onset after 1970 had a significantly higher index figure ($r=0\ 39$ $p<0\ 01$)

A summary of the statistical relations is shown in Table 9 Other analysed variables such as family history of diabetes HLA type or infection before onset were not significantly correlated to either remission period C peptide or to diabetic control

DISCUSSION

Methods Multiple regression analysis has been the main technique employed In this type of analysis an effort is made to express values obtained in the dependent variable by a function of background variables Results of statistical analysis may be presented in terms of partial regression coefficients partial correlation coefficients observed values of Student s t and the associated p values For example in the case of the relation between C peptide and insulin dose at onset other variables being held constant the regression coefficient may be considered an estimate of the difference in C peptide for two individuals who differ one unit in insulin dose but are otherwise alike as concerns the background

variables under consideration. The correlation coefficient serves as an estimate of the correlation between C peptide and insulin dose in samples comprising individuals who are alike with respect to the remaining background variables. The *t* value is obtained when testing the null hypothesis stating that any correlation between C peptide and insulin dose is of a random nature when other background variables are held constant. The *p* values yield information on the frequency of a partial correlation (or *t* value) of the size observed supposing the relationship is purely random.

In this investigation we have used the square root of C peptide as a dependent variable rather than C peptide. Such a transformation is chosen to counteract the tendency of results being dominated by a few individuals with much higher C peptide values than the rest. In consequence, however, partial regression coefficients are not very informative as the scale of measurement is transformed. Instead of such coefficients partial correlation coefficients which are less closely associated to scales of measurement have been presented. The variables (age at onset)^2 and (duration of diabetes)^2 have been included to make it possible to express non-linear relationships between these and other variables. In a retrospective study it is difficult to get reliable information about anamnestic data such as preceding infections, which to some extent may explain lack of correlations to other variables.

Results. During the remission period the beta cells produce C peptide and insulin in equimolar amounts (1, 3, 9, 13). However, even beyond the termination of this period measurable amounts of C peptide were found in 14 out of 58 patients (24.1%). Patients with prolonged ketonuria at onset and/or low insulin dose during the first 24 hours at hospital did seldom develop significant remission periods and had lower levels of C peptide later on. Patients with severe ketoacidotic symptoms and high blood glucose levels at onset also showed tendency to lower levels of C peptide (Table 7). These results support the view that an early detection of diabetes immediately followed by a vigorous treatment aiming at rapid normalization of the metabolism may save the function of some beta cells. Further support is offered by the fact that a better average diabetic control, i.e. higher index figure, was reported for patients with onset after 1970, which coincides in time with an increase in treatment intensity. A previous study from our department including a greater number of patients with onset after 1970 have shown a significant correlation between the occurrence of postinitial remission and later C peptide level (19). The fact that the same correlation was negative in the present study among patients with onset before 1970 may be due to the possibility that patients who during the 1960's had a postinitial remission period were less intensively supervised and therefore subsequently lost the function of initially saved beta cells. However, as shown in Table 7, the pattern of relationships remains unaltered even when patients without remission are analysed separately.

During the first years after onset of juvenile

diabetes insulin and C peptide serum levels are known to decrease in most patients (1 8 10 21) In the present diabetic population there was only a weak negative correlation be tween C peptide and duration however This may indicate that in those patients in whom the beta cell function has been preserved over the first few years an endogenous insulin pro duction may be present for considerably longer periods

In a previous study including more patients with shorter duration of diabetes a negative correlation was found between insulin anti bodies and C peptide (19) This could not be reconfirmed in the present study but a signifi cantly negative correlation between insulin antibodies and diabetic control was observed in contrast to other reports (6 17) This may mean that insulin antibodies disturb diabetic control by some other mechanism than through their supposed negative effect on the beta cell function (19)

During the postinitial remission period the diabetic control is excellent This may be due to the residual beta cell function as demon strated by measurable C peptide levels Our studies have shown that measurable C peptide may persist even after this period Although the fasting C peptide level does not give in formation about the ability of the beta cells to answer to naturally occurring stimuli (23) it does indicate that there is some beta cell func tion This is also supported by the correlation between C peptide and diabetic control

In conclusion our study seems to indicate that an early diagnosis with a rapid normaliza tion of the metabolism at the onset of juvenile diabetes increases the possibility to preserve some of the endogenous insulin production

RENAL GROWTH AND FUNCTION IN PATIENTS NEPHRECTOMIZED IN CHILDHOOD

A APERIA O BROBERGER I WIKSTAD and P WILTON

From the Department of Paediatrics and Paediatric Radiology Karolinska Institute St Goran s Children s Hospital Stockholm Sweden

ABSTRACT Aperia A Broberger O Wikstad I and Wilton P (Department of Paediatrics and Paediatric Radiology Karolinska Institute St Goran s Children s Hospital Stockholm Sweden) Renal growth and function in patients nephrectomized in childhood Acta Paediatr Scand 66 185 1977.—Eight patients nephrectomized in childhood were studied with regard to growth and function of the remaining kidney The age of the patients ranged between 8½ and 31 years and the follow up period was from 1 to 20 years In most of the patients repeated renal size determinations were made on postoperative urograms Normal values for kidney size in childhood are also presented The structural hypertrophy continued for at least three years after nephrectomy and was most pronounced in patients nephrectomized before three years of age When more than three years had passed after nephrectomy the remaining kidney was 35–65 % larger than normal Healthy young adults and children with a previous history of urinary tract infection served as controls for function studies The balance between glomerular and tubular function was well preserved in nephrectomized patients The renal surface area showed the same relation to GFR and to reabsorption of bicarbonate in nephrectomized patients as in controls It is therefore concluded that the increase in kidney function following unilateral nephrectomy is at least in early life primarily due to structural enlargement

KEY WORDS Nephrectomy renal hypertrophy kidney size renal function

It has been known for decades that when one kidney is removed compensatory changes occur in the remaining kidney (1 25) The mechanism of this process remains unknown (18) and many questions need to be resolved In the rat which is the most commonly studied species unilateral nephrectomy results in structural enlargement (12 22 24) as well as in increased function (12 24) of the contralateral kidney However there appears to be some dissociation between structural and functional changes (12) It is therefore uncertain to what extent increased renal function is due to structural changes of the nephron and to what extent increased function is secondary to increased blood perfusion relative to the size of the nephron It seems likely that increased function based on structural enlargement provides optimal conditions for complete preservation of renal function On the other hand increased function that is due to increased nephron perfusion might disrupt the normal relationship between glomerular perfusion glomerular filtration and tubular reabsorption which in turn would effect homeostatic efficiency of the kidney

This study concerns the relationship between renal size and renal function in nephrectomized man The function studies include determinations of both glomerular filtration rate (GFR) and tubular reabsorptive capacity Only patients nephrectomized in childhood

have been included since experimental studies suggest that structural hypertrophy differs in growing and adult animals (9 17)

MATERIAL

Eight patients five females and three males have been studied The age of the patients ranged between 8½ and 31 years Only patients with a normal remaining kidney at nephrectomy were included in this study The time that elapsed after the nephrectomy ranged between 1 and 20 years Details on the patients studied are given in Table 1 In all but one patient (K L) nephrectomy was carried out because of unilateral renal disease The parenchyma of the nephrectomized kidney was therefore generally reduced (Fig 1) At the time of the study all of the patients were in good general condition Three patients developed a urinary tract infection after surgery but not during the two years prior to the study The arterial blood pressure was normal The length and weight of the patients are presented in Fig 2 In no case did nephrectomy influence subsequent length and weight Informed consent for this study was obtained from all of the adult patients and from the parents of the children

Normal renal size was determined in 37 patients ranging in age from 2 months to 30 years All of the patients were referred for urography because of abdominal pain except for infants with a twin who had a malformation None of the patients in this group had a previous history of renal disease The length and weight of the patients were within ±2 S D of normal

Four girls 7 to 13 years old with recurrent urinary tract infection (UTI) but with normal GFR and normal response to an oral ammonium chloride load were used as a control group for the renal function study These patients have been described in a previous report from this laboratory (2)

METHODS

Determination of kidney size The size of the kidney was determined on urograms Five patients were followed with repeated urographies one to five times postoperatively for at least three years In four patients preoperative urograms were available Urography was carried out with the standard technique of anterior posterior and oblique views External ureteral compression was used in each case 0 5–1 ml/kg body weight of contrast medium (60% Urografin Scheering AG) was injected intravenously A film focus distance of 100 cm was used in all cases The size of the renal parenchyma was determined by tracing the outlines of the kidney on transparent paper The renal pelvis was not included in the tracing The traced area was measured with a planimeter All values were correlated to body surface

Renal function This study was performed in the Paediatric Department of St Goran s Hospital The children were hospitalized for one week and received a special diet containing 100–150 mmol Na/1 73 m² body surface area (BSA)/day The adults were studied as outpatients and they were instructed to follow a regular diet without excessive salt At the time of the renal function study blood samples were obtained for determination of Hb WBC SR serum sodium potassium calcium phosphate pH P_{CO_2} and bicarbonate The values were consistently normal Urine cultures before and two weeks after the renal function study were negative In all patients except

Table 1 *Clinical data of patients studied*
UTI=urinary tract infection

Patient	Sex	Age at nephrectomy	*Symptoms*	Kidney disease	Age at the time of study (y)
BL	M	6 m	Fever abdominal tumor	Hypoplastic kidney with no normal tissue	12
MR	F	9 m	UTI	Non obstructive hydronephrosis with large reflux	11
MK	M	2 y	Fever abdominal tumor	Hydronephrosis with obstruction in pelvoureteral junction	9½
ML	M	3 y	Recurrent fever UTI	Pyelonephritic kidney with tissue changes indicative of dysplasia	12
LH	F	7½ y	Recurrent UTI	Several cysts in a normal cortex Medulla fibrotic with much primitive tissue	8½
UE	F	8 y	Recurrent UTI 4 years	Polycystic renal dysplasia	19
KL	F	10½ y	Traumatic rupture	Normal kidney	31
EK	F	13 y	Recurrent back pain	Hydronephrosis with obstruction in pelvoureteral junction	29

have been included since experimental studies suggest that structural hypertrophy differs in growing and adult animals (9 17)

MATERIAL

Eight patients five females and three males have been studied The age of the patients ranged between 8½ and 31 years Only patients with a normal remaining kidney at *nephrectomy were included in this study* The time that elapsed after the nephrectomy ranged between 1 and 20 years Details on the patients studied are given in Table 1 In all but one patient (K L) nephrectomy was carried out because of unilateral renal disease The parenchyma of the nephrectomized kidney was therefore generally reduced (Fig 1) At the time of the study all of the patients were in good general condition Three patients developed a urinary tract infection after surgery but not during the two years prior to the study The arterial blood pressure was normal The length and weight of the patients are presented in Fig 2 In no case did nephrectomy influence subsequent length and weight Informed consent for this study was obtained from all of the adult patients and from the parents of the children

Normal renal size was determined in 37 patients ranging in age from 2 months to 30 years All of the patients were referred for urography because of abdominal pain except for infants with a twin who had a malformation None of the patients in this group had a previous history of renal disease The length and weight of the patients were within ±2 S D of normal

Four girls *7 to 13 years old with recurrent urinary tract* infection (UTI) but with normal GFR and normal response *to an oral ammonium chloride load were used as a control* group for the renal function study These patients have been described in a previous report from this laboratory (2)

METHODS

Determination of kidney size The size of the kidney was determined on urograms Five patients were followed with repeated urographies one to five times postoperatively for *at least three years In four patients preoperative uro*grams were available Urography was carried out with the standard technique of anterior posterior and oblique views *External ureteral compression was used in each* case 0 5–1 ml/kg body weight of contrast medium (60% Urografin Scheering AG) was injected intravenously A film focus distance of 100 cm was used in all cases The size of the renal parenchyma was determined by tracing the outlines of the kidney on transparent paper The renal pelvis was not included in the tracing The traced area was measured with a planimeter All values were correlated to body surface

Renal function This study was performed in the Paediatric Department of St Goran s Hospital The children were hospitalized for one week and received a special diet containing 100–150 mmol Na/1 73 m² body surface area (BSA)/day The adults were *studied as outpatients* and they were instructed to follow a regular diet without excessive salt At the time of the renal function study *blood samples were obtained for determination of* Hb WBC SR serum sodium potassium calcium phosphate pH P_{CO_2} and bicarbonate The values were consistently normal Urine cultures before and two weeks after the renal function study were negative *In all patients except*

one a urogram was obtained 2 to 14 days before or after the renal function study

Renal function was evaluated with a clearance technique including bladder catheterization and continuous infusion of inulin (Laevasar Gesellschaft) which was the indicator substance for glomerular filtration The study was carried out using a standardized fluid intake of approximately 0 7%/kg body weight every hour Urine was collected during 20 min periods In the middle of each period venous blood samples were withdrawn for analysis of inulin and electrolytes and prewarmed capillary blood samples were taken for determination of pH HCO_3 concentration and Pco_2 pH and bicarbonate were determined in anaerobic urine samples Urine samples were analyzed with the Astrup technique as described previously (2) After two to three control periods an intravenous infusion of 0 6 molar sodium bicarbonate was started with a stepwise increase of infusion rate After 11 to 16 periods when approximately 6 ml/kg bicarbonate had been infused the serum bicarbonate concentration had reached 30–32 mmol/l and the test was interrupted The net fluid expansion during the test averaged 2 2±0 7% of body weight

ANALYTICAL METHODS

Analyses of inulin in serum and urine were made with the anthrone method (15) Sodium concentration in serum and urine was determined with a flame photometer Blood pH bicarbonate and P_{CO_2} were determined with the Astrup method The pH of fresh blood and urine samples were determined (after equilibration with 4% and 8% carbon dioxide gas mixtures) in a pH meter 27 (Radiometer) The bicarbonate concentration of urine was calculated by using the Henderson Hasselbalch equation assuming the pH of urine to be 6 33–0 5 $\sqrt{B}$ where B represents the sum of urinary sodium and potassium concentration in mols/l For details see previous report (2) For statistical analyses the Student s t test has been used

RESULTS

Fig 3 shows the normal relationship between renal surface area and age Renal surface in relationship to body surface area falls slightly but significantly during the first 12 years of life The relationship can be described by the equation (83 70–0 1475X) (X=age in months) After the age of twelve years renal surface in relation to body surface remains constant (62±6)×10^{-4} m²/1 73 m² BSA (mean ±S D)

Renal surface area in nephrectomized patients has been expressed in % of the surface area expected for one kidney in healthy individuals of corresponding age (Fig 4) Preoperatively the healthy kidney was enlarged 107–126% of normal in patients with unilateral renal disease Following unilateral nephrectomy the healthy kidney showed a further increase in size Enlargement of the remaining kidney continued two to four years after the operation After that time the size of the renal parenchyma ranged between 135–164% of the expected size The increase in renal surface *area that occurred was the result of a homogenous* enlargement of the renal parenchyma (Fig 5) The final size of the remaining kidney appears to be inversely related to the age at which nephrectomy is performed (Fig 6)

The data from the renal function studies are summarized in Table 2 The GFR averages 4 92 l/h/1 73 m² BSA This is approximately 75% of the GFR found in healthy young adults (3) with both kidneys intact or 149% of the GFR in one normal kidney The GFR appears to be independent of the present age at this study as well as of the age at nephrectomy (Fig 7*a* and *b*) Renal tubular function was evaluated by studying the reabsorption of

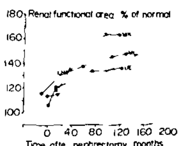

Fig 4 Postoperative increase in renal size determined on repeated urograms in five patients

Previous studies on renal size in nephrectomized man generally include only one value for each individual In this investigation the development of compensatory renal growth has been followed for the first time In all patients who were nephrectomized because of unilateral renal disease the contralateral kidney was 7–26% larger than normal at the time of surgery Removal of the diseased kidney initiated a further relative increase in renal size that continued for at least three years The finding that compensatory structural changes took place over such a long period of time was somewhat unexpected In man functional adaption to unilateral nephrectomy is generally considered to be almost complete after two weeks (11) More recent studies however show that a slight further increase can occur and that this increase is dependent on the age at which nephrectomy is carried out (4)

The size of the hypertrophied kidney at the last determination was 135 to 165% of normal In previous studies of kidney donors the size of the remaining kidney has generally not been more than 25% larger than normal (5 20) In most of those studied however the time from operation to the recording of kidney size has been shorter than 48 months The fact that renal enlargement is more pronounced in patients in the present study might depend on two factors longer observation time and younger age at which nephrectomy was performed The finding in this study that the final size of the kidney was dependent on the age at nephrectomy indicates that the second factor is also of importance

Functional adaption to nephrectomy appears to be more independent of age than structural adaption When GFR is related to body surface the values recorded in this study are well in accordance with those found in healthy kidney donors (4 19) as well as in nephrectomized children (14 23) *i e* 4 6 l/1 73 m² BSA/h Previous studies on kidney donors (21) as well as on nephrectomized children (23) have shown that the maximal transport capacity for glucose and PAH increase in proportion to the GFR in the remaining kidney This is also true for hydrogen ion excretion (7) Other tubular parameters such as phosphate and uric acid transport (21) have however been found to increase out proportion to the GFR This shows that one cannot predict the tubular changes that will occur following ablation of renal tissue but that each transport system should be analyzed individually In the present study tubular reabsorption of HCO_3 was determined since this function is of major importance for control of acid–base balance and even minor disturbances in tubular HCO_3 transport might have important clinical consequences The capacity to reabsorb HCO_3 at high serum HCO_3 levels was increased in proportion to or just above the GFR This parameter like glucose and PAH transport can be used as a quantitative measurement of proximal tubular function The renal HCO_3 threshold was slightly but not significantly lower in the nephrectomized patients The combined finding of a reduced threshold and normal maximal reabsorptive capacity may be interpreted as a sign of heterogeneity of the nephron population (10) The limited range of the HCO_3 reabsorption values when the serum HCO_3 values *were increased* suggests that even if heterogeneity occurs in the hypertrophied kidney it is not of major importance

The normal relationship between renal size and GFR as well as the relationship between renal size and tubular capacity for bicarbonate reabsorption were well preserved in all of the hypertrophied kidneys studied This makes it appear very likely that in patients nephrectomized in childhood functional adaption will be due mainly to structural enlargement of the kidney More studies are needed to show if this is also true of individuals nephrectomized in adulthood

DISCUSSION

The majority of studies concerning compensa tory hypertrophy have been carried out in rats but this species continues to grow throughout life When renal mass is removed in the adult rat the structural and functional changes are proportional to the mass of tissue removed (16) There exists however some dissociation between structural and functional adaption Some investigators have found that an in crease in GFR precedes the structural enlarge ment (22) When adaptive changes are com pleted three to four weeks after nephrectomy GFR has increased 50–90% (12 15 16) while the increase in kidney weight averages 35–50% (15 16) The increment in renal mass following unilateral nephrectomy is more pro nounced in young rats and also depends more on hyperplasia than hypertrophy of the cells (9) It has also been reported that nephrec tomy in rats younger than 30 days results in increased formation of new nephrons (6) but this has not been confirmed by other investi gators (17)

Previous studies on renal size in nephrectomized man generally include only one value for each individual In this investigation the development of compensatory renal growth has been followed for the first time In all patients who were nephrectomized because of unilateral renal disease the contralateral kidney was 7–26% larger than normal at the time of surgery Removal of the diseased kidney initiated a further relative increase in renal size that continued for at least three years The finding that compensatory structural changes took place over such a long period of time was somewhat unexpected In man functional adaption to unilateral nephrectomy is generally considered to be almost complete after two weeks (11) More recent studies however show that a slight further increase can occur and that this increase is dependent on the age at which nephrectomy is carried out (4)

INFANTILE PERIARTERITIS NODOSA OR MUCOCUTANEOUS LYMPH NODE SYNDROME

A report on four cases and diagnostic considerations

HANS AHLSTROM NILS RUNE LUNDSTRÖM WIGHER MORTENSSON GOREL ÖSTBERG and KURT LANTORP

From the Departments of Paediatrics and Radiology University Hospital Lund the Department of Pathology General Hospital Malmo and the Department of Infectious Diseases County Hospital Jonkoping Sweden

ABSTRACT Ahlstrom H Lundstrom N R Mortensson W Östberg G and Lantorp K (Department of Paediatrics and Radiology University Hospital Lund the Department of Pathology General Hospital Malmo and the Department of Infectious Disease County Hospital Jonkoping Sweden) Infantile periarteritis nodosa or mucocutaneous lymph node syndrom A report on four cases and diagnostic considerations Acta Paediatr Scand 66 193 1977.—Coronary artery aneurysm in childhood is a rare disease and has in most cases been ascribed to infantile periarteritis nodosa (IPN) In recent years a mucocutaneous lymph node syndrom (MLNS) has been found almost exclusively in Japan first described by Kawasaki 1967 this disease frequently involves the coronary arteries and myocardium Four cases with coronary aneurysms are presented from Sweden and seem to be the first described from Scandinavia Three of these patients died a sudden death with cardiac arrest Since MLNS and IPN have identical clinical and pathological features we suggest that MLNS and IPN constitute a pathologic entity and that to separate them on a clinical or histological basis is nonsensical The risk of coronary aneurysm and possible sudden death must be considered in patients with uncharacteristic symptoms including prolonged fever conjunctivitis exanthema lesions in the oral mucosa elevated sedimentation rate and leukocytosis

KEY WORDS Infantile periarteritis nodosa mucocutaneous lymph node syndrome coronary artery aneurysm Kawasakis disease

Aneurysms of the coronary arteries are rarely encountered in childhood They have previously been ascribed to infantile polyarteritis nodosa (IPN) (7) One of us has earlier (27) reported one case and then commented on the mucocutaneous symptoms finding that those were reported in 70% of about 100 cases published earlier as IPN Except for a few instances the diagnoses of coronary aneurysms were made at necropsy and the condition was thought to involve a very high mortality rate Recently however coronary aneurysms and myocardial infarction were found to be the cause of death in children accounted to suffering from a mucocutaneous lymph node syndrome (MLNS) not previously described (6 11 12 13 24) This disease has been reported almost exclusively from Japan and based on an investigation of 7000 cases the mortality rate was found to be 1 or 2%

The clinical features of IPN and MLNS are very similar including e g prolonged fever exanthema conjunctivitis lesions in the oral mucoza elevated sedimentation rate and leukocytosis In this report we present four cases from southern Sweden with similar illness of

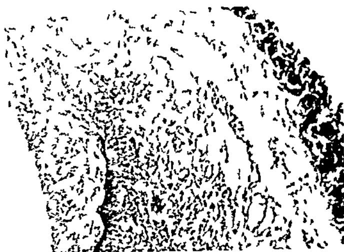

Fig 3 Case 1 Longitudinal section from right coronary artery Widespread inflam mation in all parts of the vessel wall de struction of elastic lamina in the upper part Fibrincoated epicardium to the right H–E ×88

and tortuous (Fig 4) and the proximal part of the left descending branch contained a 1 cm thick thrombus The vessel had ruptured at this site The lungs liver and spleen were heavy and congested

Microscopy disclosed partly destroyed walls of the coronary arteries with widespread acute inflammation with polymorphonuclear leucocytes (Fig 5) In the left ventricular myocardium there were fresh necroses In both iliac arteries and in branches of the mesenteric and the perirenal arteries areas of acute inflammation were present Millimeter wide arteries in the periadrenal fat testis and epididymis showed fibrinoid necrosis of the vessel wall with infiltration of polymorphonuclear leuko-cytes

Case 3

A 4-year-old boy was admitted to hospital in april 1966 be cause of persistent fever sore throat and enlargement of cervical lymph nodes in spite of penicillin and ampicillin treatment for one week A few days later the patient s hands and ankles became swollen and tender Examina tion of the blood revealed a leucocytosis (maximum 000/mm) with a pronounced neutrophilia Urine and CSF analyses were normal Protein electrophoresis re vealed an increased α_2-globuline concentration No bac terial growth was shown in cultures of blood urine CSF and stools No virus could be i olated ECG was initially normal but later deep Q waves and ST T abnormalities ap-peared in the left precordial leads

In the summer of 1966 the heart was normal at roentgen examination In may 1967 the heart volume was moderate ly increased During the autumn the volume decreased somewh t and later a sl ght enlargement of the heart was invariably demonstrated at repeated examinations

The child improved and the fever and arthritis dis appeared after three weeks He was continuously treated with peni illin When discharged from hospital he was in good condition However an abnormal ECG pattern and a card a enlargement persisted

Cardia catheterizatio n and angiocardiography with in jection of contrast medium into the left ventricle was car ried out in 1969 Two aneurysms were demonstrated in the right coronary artery and in the left coronary artery there was an aneurysm at the arterial bifurcation (Fig 6*a*) A few months later the proximal part of the right coronary aneurysms was partly filled with a thrombotic mass and the artery was occluded close to this aneurysm The distal part of the right coronary artery was filled in a retrograde direction from the left circumflex artery

Two years later the right coronary artery was totally occluded close to its origin from the aorta and the aneu rysm of the left coronary artery had increased in size (Fig 6*b*)

The boy is now 13 years old and is in good condition He has no angina pectoris He has been treated with anti coagulants during the past six years

Fig 4 Case 2 Opened heart Right coronary artery (at the left part of the picture) cm wide thin walled tortuous with inbulging ridges

Fig 1 Case 1 Chest examination one day prior to death Heart volume is increased There is a bulge at the left of the heart which was not present at previous examination

obscure origin who all developed aneurysms of the coronary arteries

CASE HISTORIES

Case 1

A previously healthy 6-month old girl was admitted to hospital because of persistent high feber sore throat conjunctivitis signs of meningitis diarrhoea and a maculopapular exanthema over the trunk In addition oedema in the face and on the hands and a moderate hepatomegalia were noticed on admittance to hospital Laboratory examination of the blood revealed leucocytosis (at most 29000/mm³) and marked neutrophilia accelerated erythrocyte sedimentation rate (maximum 70 mm) and positive CRP Serum protein electrophoresis revealed increased α_2 globuline and IgM concentration and a pathological band in the gamma region on immune electrophoresis analysis LDH was slightly elevated Analysis of the cerebrospinal fluid (CSF) revealed 20 mononuclear leucocytes/mm³ and a protein content of 0 50 g/l Urine analysis was without remark Scintigraphy of the liver and the brain were normal EEG was normal Sinus tachycardia was constantly found at ECG which otherwise was normal at repeated examinations Bacterial cultures from the throat nose urine stool and CSF were all negative Complement fixation tests were negative and no virus could be isolated

Normal appearance of heart and lungs was demonstrated at repeated roentgen examinations during the initial period

The infant was treated with different antibiotics (penicillin gentamycin and cephalothin) without any effect on the temperature or the general condition After administration of hydrocortisone (?00 mg/day) the temperature normalized and the infant improved within a few days The fever reappeared when the hydrocortisone treatment was stopped The patient was then given prednisolon orally the temperature decreased the exanthema disappeared and the infant improved However after three weeks treatment the infant died suddenly

On the day prior to death roentgen examination showed that the heart volume had increased substantially and a bulge had appeared on the upper left border of the heart (Fig 1)

Necropsy A small amount of coagulated blood was found in the pericardial sac and a fibrinous pericarditis on the anterior cardiac surface The heart was enlarged mainly due to left ventricular hypertrophy The coronary arteries were profoundly dilated and tortuous (Fig 2) The liver was enlarged and congested

Microscopic examination revealed widespread inflammation of the coronary arteries with oedema and destruction of parts of the arterial wall Polymorphonuclear leucocytes predominated in the exudate (Fig 3) Similar inflammatory changes were also seen in small areas in the carotid and superior mesenteric arteries and in some veins in the lungs and the liver Other organs were normal

Case 2

A 18 month old boy was admitted to hospital because of an obscure exanthema The exanthema disappeared and the boy was sent home

Six weeks later the patient became ill with high fever exanthema and cough scarlet fever was suspected Treatment with penicillin had no effect After a few days desquamation of the skin was noticed on the fingers A moderate fever persisted the appetite was poor and the patient was remarkably tired He died from a sudden cardiac arrest at home

Necropsy A 55 mm thick fresh dark red coagulum surrounded the heart The coronary arteries were dilated

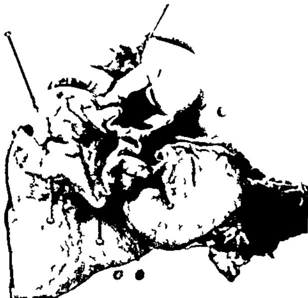

Fig 2 Case 1 Part of the heart with right coronary cut open greatly dilated and tortuous The pericardium is fibrin coated and thickened

Fig 3 Case 1 Longitudinal section from right coronary artery Widespread inflammation in all parts of the vessel wall destruction of elastic lamina in the upper part Fibrincoated epicardium to the right H–E × 88

and tortuous (Fig 4) and the proximal part of the left descending branch contained a 1 cm thick thrombus The vessel had ruptured at this site The lungs liver and spleen were heavy and congested

Microscopy disclosed partly destroyed walls of the coronary arteries with widespread acute inflammation with polymorphonuclear leucocytes (Fig 5) In the left ventricular myocardium there were fresh necroses In both iliac arteries and in branches of the mesenteric and the perirenal arteries areas of acute inflammation were present Millimeter wide arteries in the periadrenal fat testis and epididymis showed fibrinoid necrosis of the vessel wall with infiltration of polymorphonuclear leukocytes

Case 3

On the day prior to death roentgen examination showed that the heart volume had increased substantially and a bulge had appeared on the upper left border of the heart (Fig 1)

Necropsy A small amount of coagulated blood was found in the pericardial sac and a fibrinous pericarditis on the anterior cardiac surface The heart was enlarged mainly due to left ventricular hypertrophy The coronary arteries were profoundly dilated and tortuous (Fig 2) The liver was enlarged and congested

Microscopic examination revealed widespread inflammation of the coronary arteries with oedema and destruction of parts of the arterial wall Polymorphonuclear leucocytes predominated in the exudate (Fig 3) Similar inflammatory changes were also seen in small areas in the carotid and superior mesenteric arteries and in some veins in the lungs and the liver Other organs were normal

Case 2

A 18 month old boy was admitted to hospital because of an obscure exanthema The exanthema disappeared and the boy was sent home

Six weeks later the patient became ill with high fever exanthema and cough scarlet fever was suspected Treatment with penicillin had no effect After a few days desquamation of the skin was noticed on the fingers A moderate fever persisted the appetite was poor and the patient was remarkably tired He died from a sudden cardiac arrest at home

Necropsy A 55 mm thick fresh dark red coagulum surrounded the heart The coronary arteries were dilated

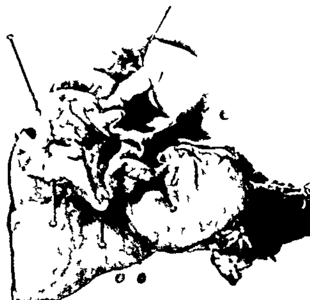

Fig 2 Case 1 Part of the heart with right coronary cut open greatly dilated and tortuous The pericardium is fibrin coated and thickened

Fig 3 Case 1 Longitudinal section from right coronary artery Widespread inflammation in all parts of the vessel wall destruction of elastic lamina in the upper part Fibrincoated epicardium to the right H-E × 88

and tortuous (Fig 4) and the proximal part of the left descending branch contained a 1 cm thick thrombus The vessel had ruptured at this site The lungs liver and spleen were heavy and congested

Microscopy disclosed partly destroyed walls of the coronary arteries with widespread acute inflammation with polymorphonuclear leucocytes (Fig 5) In the left ventricular myocardium there were fresh necroses In both iliac arteries and in branches of the mesenteric and the perirenal arteries areas of a ute inflammation were present Millimeter wide arteries in the periadrenal fat testis and epididymis showed fibrinoid necrosis of the vessel wall with infiltration of polymorphonuclear leukocytes

Case 3

A 4-year-old boy was admitted to hospital in april 1966 because of persistent fever sore throat and enlargement of cervical lymph nodes in spite of penicillin and ampicillin treatment for one week A few days later the patient s hands and ankles became swollen and tender Examination of the blood revealed a leucocytosis (maximum 000/mm) with a pronounced neutrophilia Urine and CSF analyses were normal Protein electrophoresis revealed an increased α globuline concentration No bacterial growth was shown in cultures of blood urine CSF and stools No virus could be isolated ECG was initially normal but later deep Q waves and ST T abnormalities appeared in the left precordial leads

In the summer of 1966 the heart was normal at roentgen examination In may 1967 the heart volume was moderately increased During the autumn the volume decreased somewhat and l ter a slight enlargement of the heart was invariably demonstrated at repeated examinations

The child improved and the fever and arthritis disappeared after three weeks He was continuously treated with pen cillin When di charged fr m hospital he was in good conditi n H wever an abnormal ECG pattern and a card ac enlargement persisted

Cardiac catheterization and angiocardiography with injection of contrast medium into the left ventricle was carried out in 1969 Two aneurysms were demonstrated in the right coronary artery and in the left coronary artery there was an aneurysm at the arterial bifurcation (Fig 6*a*) A few months later the proximal part of the right coronary aneurysms was partly filled with a thrombotic mass and the artery was occluded close to this aneurysm The distal part of the right coronary artery was filled in a retrograde direction from the left circumflex artery

Two years later the right coronary artery was totally occluded close to its origin from the aorta and the aneurysm of the left coronary artery had increased in size (Fig 6*b*)

The boy is now 13 years old and is in good condition He has no angina pectoris He has been treated with anticoagulants during the past six years

Fig 4 Case Opened heart Right coronary artery (at the left part of the picture) cm wide thin walled tortuous with inbulging ridges

Fig 1 Case 1 Chest examination one day prior to death *Heart volume is increased There is a bulge at the left of* the heart which was not present at previous examination

obscure origin who all developed aneurysms of the coronary arteries

CASE HISTORIES

Case 1

A previously healthy 6-month old girl was admitted to hospital because of persistent high feber sore throat conjunctivitis signs of meningitis diarrhoea and a maculopapular exanthema over the trunk In addition oedema in the face and on the hands and a moderate hepatomegalia were noticed on admittance to hospital Laboratory examination of the blood revealed leucocytosis (at most 29000/mm³) and marked neutrophilia accelerated erythrocyte sedimentation rate (maximum 70 mm) and positive CRP Serum protein electrophoresis revealed increased α_2 globuline and IgM concentration and a pathological band in the gamma region on immune electrophoresis analysis LDH was slightly elevated Analysis of the cerebrospinal fluid (CSF) revealed 20 mononuclear leucocytes/mm³ and a protein content of 0 50 g/l Urine analysis was without remark Scintigraphy of the liver and the brain were normal EEG was normal Sinus tachycardia was constantly found at ECG which otherwise was normal at repeated examinations Bacterial cultures from the throat nose urine stool and CSF were all negative Complement fixation tests were negative and no virus could be isolated

Normal appearance of heart and lungs was demonstrated at repeated roentgen examinations during the initial period

The infant was treated with different antibiotics (penicillin gentamycin and cephalothin) without any effect on the temperature or the general condition After administration of hydrocortisone (200 mg/day) the temperature normalized and the infant improved within a few days The fever reappeared when the hydrocortisone treatment was stopped The patient was then given prednisolon orally the temperature decreased the exanthema disappeared and the infant improved However after three weeks treatment the infant died suddenly

On the day prior to death roentgen examination showed that the heart volume had increased substantially and a bulge had appeared on the upper left border of the heart (Fig 1)

Necropsy A small amount of coagulated blood was found in the pericardial sac and a fibrinous pericarditis on the anterior cardiac surface The heart was enlarged mainly due to left ventricular hypertrophy The coronary arteries were profoundly dilated and tortuous (Fig 2) The liver was enlarged and congested

Microscopic examination revealed widespread inflammation of the coronary arteries with oedema and destruction of parts of the arterial wall Polymorphonuclear leucocytes predominated in the exudate (Fig 3) Similar inflammatory changes were also seen in small areas in the carotid and superior mesenteric arteries and in some veins in the lungs and the liver Other organs were normal

Case 2

A 18 month old boy was admitted to hospital because of an obscure exanthema The exanthema disappeared and the boy was sent home

Six weeks later the patient became ill with high fever exanthema and cough scarlet fever was suspected Treatment with penicillin had no effect After a few days desquamation of the skin was noticed on the fingers A moderate fever persisted the appetite was poor and the patient was remarkably tired He died from a sudden cardiac arrest at home

Necropsy A 55 mm thick fresh dark red coagulum surrounded the heart The coronary arteries were dilated

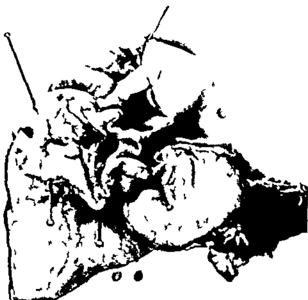

Fig 2 Case 1 Part of the heart with right coronary cut open greatly dilated and *tortuous* The pericardium is fibrin coated and thickened

Table 1 *Common clinical features in infantile periarteritis nodosa (IPN) and the mucocutaneous lymph node syndrome (MLNS) compared with symptoms and signs in the present cases*

	IPN	MLNS	Present cases 1	2	3	4
Prolonged fever not responding to antibiotics	+	+	+	+	+	+
Congestion of ocular conjunctive	+	+	+	?	−	+
Lesions of the lips and oral cavity	+	+	+	+	+	+
Changes in hands and feet	+	+	+	+	+	−
Polymorphous exanthema	+	+	+	+	?	+
Acute nonsuppurative swelling of cervical lymph nodes	+	+	+	?	+	+
Cardiovascular signs	+	+	+	+	+	+
Diarrhoea	+	+	+	−	−	−
Proteinuria	+	+	+	−	−	−
Leucocytosis with neutrophilia	+	+	+	?	+	+
Increased ESR	+	+	+	?	+	+
Positive CRP	+	+	+	?	?	
Increased serum α_2-globulin	+	+	+	?	+	?
Negative AST	+	+	+	?	+	+

Necropsy The pericardium contained 300 ml clotted blood The main branches of the left coronary artery were widely almost aneurysmatically dilated but narrowed gradually towards the heart apex The anterior descending branch contained a large thrombus The myocardium was normal the lungs were heavy and oedematous and a small amount of transsudate was present in the pleural sac

Microscopically the walls of the coronary artery were largely destroyed by widespread inflammation

DISCUSSION

The description in the literature of the clinical history of IPN and MLNS are identical in most respects (2 4 5 8 13 14 15 18 20 21 22) The present four cases share many characteristic symptoms with both IPN and MLNS (Table 1) The fatal outcome in three of the children was quite unexpected It seems impossible to differentiate between IPN and MLNS on clinical and laboratory grounds However the prognosis of the two diseases is considered to differ profoundly

According to Kawasaki et al (13) the pathological findings in MLNS and IPN are identical they differ however in their clinical evolution The authors added that the clinical picture of IPN has got only scant descriptions

The necropsy findings in our cases are almost identical to those previously reported in both IPN and MLNS Thus not even the histological examination can differentiate the two conditions

In the original description of polyarteritis nodosa by Kussmaul & Maier (16) it was stated that the disease affected medium sized arteries mainly in the splanchnic area Similar changes were noted by Arkin (1) Since then varying arterial changes have been described as polyarteritis nodosa including changes in fairly small arteries detectable at histological examination only Clinical investigations and animal experiments led Zeek et al (25 26) to set up more clearly defined criteria on polyarteritis nodosa They stated that only medium sized arteries should be affected and arteritis not fulfilling the criteria should be designed as hypersensitivity angiitides According to Zeek s criteria our cases represent polyarteritis nodosa Current textbooks however have wider and more varying criteria of polyarteritis nodosa

The etiology of periarteritis nodosa and MLNS is unknown It is notable that rickettsia like bodies have been found in biopsy specimens from patients with MLNS (9) as Treponema pallidum and rickettsia are the

Fig 5 Case 2 Transverse section from middle part of left descending coronary artery Greatly widened artery with inflammation spreading into the surrounding fat Parts of the media preserved in the lower middle otherwise destroyed wall H-E × 88

Case 4

A previously healthy 9 year old boy was admitted to hospital because of exanthema and continuous high fever in spite of a four days treatment with ampicillin At admission he was remarkably tired had a stiff neck conjunctivitis swollen and red tonsils and a fine papulous exanthema A few days later a strawberry tongue was noticed

Analysis of the blood showed leucocytosis (14 000/ mm³) and a neutrophilia The sedimentation rate was 81 mm/hr Analysis of CSF revealed 16 leucocytes/mm³ Urine analysis was normal Bacterial cultures from the urine and throat were negative ECG and roentgen examination of the chest were normal

The boy was treated with penicillin and meticillin but the high fever persisted He had no signs of cardiac failure Nine days after admission to hospital he was found dead in bed

Fig 6 (*a*) Case 3 Left ventricular angiocardiography performed at the age of 8 years The right coronary artery is wide and is the site of two aneurysms (arrows) In the left coronary artery there is an aneurysm at the bifurcation (*b*) Supravalvular aortography performed at the age of 12 years The right coronary artery is now totally occluded 5–6 mm from where it branches from the aorta Proximally to the occlusion small branches appear supplying the right ventricle The left sided aneurysm has increased in size

Table 1 *Common clinical features in infantile periarteritis nodosa (IPN) and the mucocutaneous lymph node syndrome (MLNS) compared with symptoms and signs in the present cases*

The etiology of periarteritis nodosa and MLNS is unknown It is notable that rickettsia like bodies have been found in biopsy specimens from patients with MLNS (9) as Treponema pallidum and rickettsia are the

cause of other types of arteritis e g syphilis and Rocky Mountain spotted fever

In the light of the general experience that coronary aneurysm is a very rare disease in childhood we find the accumulation of such cases in a small area of Sweden with about 2 million inhabitants exceptional It is also remarkable that so few reports have appeared from other parts of the world since the original report of Kawasaki (3 10 17 19 23) This may partly be due to ignorance of the disease and the uncharacteristic and obscure symptoms

INSULIN AND GLUCAGON RESPONSE TO ARGININE INFUSION IN CYSTIC FIBROSIS

AILEEN O B REDMOND K D BUCHANAN and ELIZABETH R TRIMBLE

From The Royal Belfast Hospital for Sick Children Belfast and The Department of Medicine Queen s University Belfast Northern Ireland

ABSTRACT Redmond A O B Buchanan K D and Trimble E R (The Royal Belfast Hospital for Sick Children Belfast and The Department of Medicine Queen s University Belfast) Insulin and glucagon response to arginine infusion in cystic fibrosis Acta Paediatr Scand 66 199 1977.—The glucagon and insulin responses to intravenous arginine were studied in 17 children with cystic fibrosis and in 9 control children It was found that the overall secretion of insulin was diminished however four of the CF children did have a normal output The glucagon responses did not parallel those of insulin The glucagon output varied in the CF children—seven had normal four excessively high and six low output Three of the four children with extremely high output had more severe disease and were below the third centile on the weight chart These four had a fasting hypoglycaemia and also a very low glucose and insulin response We have confirmed diminished insulin secretion in cystic fibrosis but diminished glucagon secretion was only noted when some insulin secretion was preserved The high levels of glucagon seen in the most insulin deficient subjects may be derived from extrapancreatic sources or may be associated with stress reaction in these patients who also had most severe pulmonary involvement The data would be consistent with diminished glucagon and insulin secretion from the pancreas but as the disease progresses an excessive secretion of extra pancreatic glucagon results

KEY WORDS Cystic fibrosis arginine glucagon

It has been recognized for some time that there is an increased incidence of diabetes mellitus in cystic fibrosis (21) Diminished insulin output in cystic fibrosis in response to oral and intravenous glucose has been reported by Milunsky (19) Milner (18) and Handwerger (9) No absolute cause has been found to account for the insulinopenia Several possibilities have been suggested Want (26) postulated that the gene for cystic fibrosis and diabetes are linked Charles & Kelley (6) in 1961 suggested that the excretory cell defect seen in cystic fibrosis also occurs in the beta cells Handwerger (9) thought the insulinopenia was due to destruction of the islets of Langerhans by pancreatic fibrosis or architectural disorganisation The possibility of a defect in the entero insular axis was considered by Milner (18) in 1969 Several publications recently would suggest that glucagon may be implicated in the aetiology of diabetes mellitus (4 24)

In order to see if glucagon secretion had any hand to play in the increased incidence of diabetes in cystic fibrosis or if the glucagon output was also diminished we investigated children with cystic fibrosis using arginine intravenously as a stimulus to both alpha and beta cells

METHODS

Seventeen children with cystic fibrosis aged between 2 and 17 years mean age 6 4 years diagnosed by clinical signs and by elevated sweat electrolytes (pilocarpine

cause of other types of arteritis e g syphilis and Rocky Mountain spotted fever

In the light of the general experience that coronary aneurysm is a very rare disease in childhood we find the accumulation of such cases in a small area of Sweden with about 2 million inhabitants exceptional It is also remarkable that so few reports have appeared from other parts of the world since the original report of Kawasaki (3 10 17 19 23) This may partly be due to ignorance of the disease and the uncharacteristic and obscure symptoms

INSULIN AND GLUCAGON RESPONSE TO ARGININE INFUSION IN CYSTIC FIBROSIS

AILEEN O B REDMOND K D BUCHANAN and ELIZABETH R TRIMBLE

From The Royal Belfast Hospital for Sick Children Belfast and The Department of Medicine Queen s University Belfast Northern Ireland

ABSTRACT Redmond A O B Buchanan K D and Trimble E R (The Royal Belfast Hospital for Sick Children Belfast and The Department of Medicine Queen s University Belfast) Insulin and glucagon response to arginine infusion in cystic fibrosis Acta Paediatr Scand 66 199 1977 —The glucagon and insulin responses to intravenous arginine were studied in 17 children with cystic fibrosis and in 9 control children It was found that the overall secretion of insulin was diminished however four of the CF children did have a normal output The glucagon responses did not parallel those of insulin The glucagon output varied in the CF children—seven had normal four excessively high and six low output Three of the four children with extremely high output had more severe disease and were below the third centile on the weight chart These four had a fasting hypoglycaemia and also a very low glucose and insulin response We have confirmed diminished insulin secretion in cystic fibrosis but diminished glucagon secretion was only noted when some insulin secretion was preserved The high levels of glucagon seen in the most insulin deficient subjects may be derived from extrapancreatic sources or may be associated with stress reaction in these patients who also had most severe pulmonary involvement The data would be consistent with diminished glucagon and insulin secretion from the pancreas but as the disease progresses an excessive secretion of extra pancreatic glucagon results

KEY WORDS Cystic fibrosis arginine glucagon

It has been recognized for some time that there is an increased incidence of diabetes mellitus in cystic fibrosis (21) Diminished insulin output in cystic fibrosis in response to oral and intravenous glucose has been reported by Milunsky (19) Milner (18) and Handwerger (9) No absolute cause has been found to account for the insulinopenia Several possibilities have been suggested Want (26) postulated that the gene for cystic fibrosis and diabetes are linked Charles & Kelley (6) in 1961 suggested that the excretory cell defect seen in cystic fibrosis also occurs in the beta cells Handwerger (9) thought the insulinopenia was due to destruction of the islets of Langerhans by pancreatic fibrosis or architectural disorganisation The possibility of a defect in the entero insular axis was considered by Milner (18) in 1969 Several publications recently would suggest that glucagon may be implicated in the aetiology of diabetes mellitus (4 24)

In order to see if glucagon secretion had any hand to play in the increased incidence of diabetes in cystic fibrosis or if the glucagon output was also diminished we investigated children with cystic fibrosis using arginine intravenously as a stimulus to both alpha and beta cells

METHODS

Seventeen children with cystic fibrosis aged between ? and 1? years mean age 6 4 years diagnosed by clinical signs and by elevated sweat electrolytes (pilocarpine

iontophoresis) were studied and compared with nine control children aged between 3 and 10 years mean age 7 8 years Informed consent was obtained from the parents of all the children studied The control children were healthy children who had recovered from a minor illness All the children were tested after an overnight fast A polythene cannula was inserted in an arm vein and a fasting blood sample for blood glucose insulin and glucagon taken An infusion of 10% i arginine hydrochloride 0 5 g/kg body weight was given over a 30 min period Fifteen minutes after the start of the infusion a second sample was taken and again at 30 45 and 60 min The blood was placed in pre-cooled heparinized tubes at 4 C and transported in ice to the laboratory where it was centrifuged at 4 C Plasma glucose was measured by a micro technique (22) Insulin and glucagon were measured by radioimmunoassay

Radioimmunoassay technique

The plasma for insulin was kept frozen at −20 C until assay The assay could detect 0 5 U/ml and used a single antibody and charcoal separation technique

Glucagon assay

Blood samples for glucagon assay were taken into chilled heparinized tubes centrifuged at 4 C and the plasma extracted by the method of Heding (10) The extracts were reconstituted prior to assay in phosphate buffer pH 7 4 0 04 M Glucagon ^{125}I was prepared according to the method of Jorgensen & Larsen (11) The separation method used was serum and dextran-coated charcoal (3) Two antibodies raised to pancreatic glucagon were used in the glucagon assay viz YY89 at a final dilution of 1 45000 and YY57 at a final dilution of 1 22500 YY89 reacts with the C terminal region of glucagon and YY57 with the N terminal portion of glucagon (8) YY89 in classical terminology has been considered to be pancreas specific and YY57 to be non specific and measure total glucagon like immunoreactivity (GLI) However we have found that some species of gut GLI react with YY89 (8) and some species of pancreatic GLI do not react with YY89 (7) For this reason we have departed from the usual terminology of pancreatic glucagon and total GLI and refer to the material measured by YY89 as C terminal GLI (C-GLI) and that by YY57 as N terminal GLI (N GLI) This takes account of the lack of knowledge concerning the forms of GLI in the tissues and circulation The assays can detect between 10 and 20 pg/ml of glucagon No cross reaction has been noted with other gut and Islet hormones including insulin (Human MRC Standard) gastric inhibitory polypeptide and motilin (both gifts from J Brown) cholecystokininpancreozymin and vasoactive intestinal peptide (both gifts from V Mutt) and human synthetic gastric (ICI) The assay has been reported in detail elsewhere (5)

For simplicity we will henceforth refer to our measurement of C-GLI as glucagon (Only values of glucagon measured by the C terminal reactive antibody being given)

RESULTS

In the nine control children the infusion of arginine caused a rise of plasma glucagon and insulin in 15 min reaching a maximum at 30 min The mean glucagon (Table 2) fasting level of 34 pg/ml rose to a maximum of 246 pg/ml All the children demonstrated a rise greater than 100 pg/ml Insulin rose in all the control children from a fasting mean of 3 µU/mol to a peak of 55 µU/ml at 30 min The mean fasting glucose concentration increased from 71 mg/100 ml by an average increase of 20 mg/100 ml

Considering the 17 cystic fibrosis children as a group the blood sugar response closely parallels the rise seen in the control group with mean peak at 30 min being 85 mg/100 ml The rise of plasma glucagon in the cystic fibrosis group was similar to the controls but the cystic fibrosis group showed a smaller insulin response (mean peak value 22 µU/ml) How

ever four of the children had a response within normal range

When the glucagon results from the cystic fibrosis patients were analysed separately it appeared that there were three different patterns of response—high normal and low (Fig 1) (High demonstrated a rise greater than 600 pg/ml normal response was greater than 100 pg/ml and low was less than 100 pg/ml)

There were six children in the low response group seven in the normal and four in the high response group In the low response group the mean insulin response was not significantly different from the control group The blood sugar closely followed the control response the only significant difference being at 45 min level In the normal group the glucagon pattern closely followed the controls but there was significant differences in 45 min level ($p<0.05$) The insulin secretion was significantly lower than the controls at 30 min ($p<0.05$)

The third group the high glucagon responders presented interesting findings Of the four children in this group three were classified as having severe lung disease with exocrine pancreatic deficiency while the fourth child had moderate disease and no clinical evidence of malabsorption The mean fasting glucagon level was considerably elevated at 409 pg/ml and the level rose to a maximum of >1 085 pg/ml at 30 min the difference from the controls being significant at all times ($p<0.0025$) The insulin output in contrast was low with significant differences from controls at 30 min ($p<0.05$)

In view of the low glucose response in these four children we considered the possibility that the glycogen stores in the liver were depleted Two of the children in this group were given i v glucagon and an adequate rise in blood sugar was obtained (Table 3)

excessive secretion which may be from extrapancreatic sources It is possible that depletion of glucagon and insulin within the pancreas may act as a stimulus to the secretion of extra pancreatic glucagon A recent study by Kalk et al (13) has shown elevated fasting glucagon levels and increased responses to intravenous tolbutamide in subjects with severe chronic pancreatitis

In addition excessive secretion of extra pancreatic glucagon is usually not seen unless there is associated insulin deficiency such as in the studies by Kalk et al (12) in patients with chronic pancreatitis and in the studies by Vranic et al (25) and Matsuyama & Foa (16) in dogs Our results would be entirely consistent with this in that it was only the most severely insulin deficient children who had such excessive glucagon responses whereas the children with normal insulin secretion had defective glucagon secretion Our results would be consistent with the conclusions that secretion of insulin and glucagon from the pancreas may be deficient in children with cystic fibrosis but when the insulin deficiency becomes severe high glucagon levels may occur the source of this glucagon however may be extra pancreatic

DISCUSSION

Stahl et al (23) demonstrated a diminished insulin and glucagon output in response to arginine in children with cystic fibrosis favouring the hypothesis that the endocrine part of the pancreas in cystic fibrosis is involved in a similar process to that affecting the exocrine cells

We found an overall diminished output of insulin in the 17 children studied 4 of them did have a normal output The glucagon response was variable The basal fasting glucagon level was higher in the children with cystic fibrosis and the response to arginine varied from very low to excess The most interesting group were four children who had a very high glucagon response following arginine and also had a high fasting glucagon level This was associated with low fasting blood sugar the glucose and insulin responses to arginine being very low It is possible that the high glucagon response could be secondary to hypoglycaemia (15) All children studied were fasted for a similar period and in view of the apparently normal glycogen stores and the normal response to glucagon in two of the children in this particular group we are unable to explain the hypoglycaemia

Porte et al (20) have shown low circulating insulin levels following epinephrine infusion High circulating catecholamines have been reported by Barbero & Braddock (1) in cystic fibrosis We considered this a possible reason for the insulinopenia However Handwerger et al (9) found that an infusion of phentolamine given two hours after a GTT caused no change in the insulin level Hence it is unlikely that a raised circulating catecholamines could account for the low insulin/glucagon ratio in these four children Raised glucagon levels have been found in certain states associated with increased metabolic rate such as following burns (27) and trauma (17) Two other conditions associated with high glucagon levels are liver cirrhosis (14) and renal failure (2) but there was no evidence to suggest the presence of either of these two conditions in the cystic fibrosis patients studied here

Analogous results have been described in chronic pancreatitis (12) in association with low insulin response

At the present time we cannot state with certainty the sources of the circulating glucagon which are measuring by radioimmunoassay Our pancreatic glucagon antiserum reacts with the C Terminal portion of the glucagon molecule and this has been thought to be associated with a pancreatic glucagon specific antiserum This antiserum has low cross reactivity with extracts of gut but recent studies from our laboratory would suggest that there are some materials particularly in the stomach and colon that will cross react with this antiserum (7) In addition studies in dogs have suggested that the proximal gastrointestinal tract contains material very similar to pancreatic glucagon and indeed circulating pancreatic glucagon has been found to rise following pancreatectomy (16 25)

It is therefore possible that the glucagon levels which we are recording in this study especially in the insulinopenia patients are being derived from extra pancreatic sources Unless glucagon radioimmunoassays are modified and improved to recognize this the question will remain unanswered

We can conclude that insulin secretion is depleted in the majority of patients with cystic fibrosis However the conclusions with regard to glucagon secretion must remain guarded Some children do have diminished glucagon secretion but others have apparently

excessive secretion which may be from ex trapancreatic sources It is possible that deple tion of glucagon and insulin within the pancreas may act as a stimulus to the secretion of extra pancreatic glucagon A recent study by Kalk et al (13) has shown elevated fasting glucagon levels and increased responses to in travenous tolbutamide in subjects with severe chronic pancreatitis

In addition excessive secretion of extra pancreatic glucagon is usually not seen unless there is associated insulin deficiency such as in the studies by Kalk et al (12) in patients with chronic pancreatitis and in the studies by Vra nic et al (25) and Matsuyama & Foa (16) in dogs Our results would be entirely consistent with this in that it was only the most severely insulin deficient children who had such exces sive glucagon responses whereas the children with normal insulin secretion had defective glucagon secretion Our results would be con sistent with the conclusions that secretion of insulin and glucagon from the pancreas may be deficient in children with cystic fibrosis but when the insulin deficiency becomes severe high glucagon levels may occur the source of this glucagon however may be extra pan creatic

DISCUSSION

Stahl et al (23) demonstrated a diminished insulin and glucagon output in response to arginine in children with cystic fibrosis favouring the hypothesis that the endocrine part of the pancreas in cystic fibrosis is involved in a similar process to that affecting the exocrine cells

We found an overall diminished output of insulin in the 17 children studied 4 of them did have a normal output The glucagon response was variable The basal fasting glucagon level was higher in the children with cystic fibrosis and the response to arginine varied from very low to excess The most interesting group were four children who had a very high glucagon response following arginine and also had a high fasting glucagon level This was associated with low fasting blood sugar the glucose and insulin responses to arginine being very low It is possible that the high glucagon response could be secondary to hypoglycaemia (15) All children studied were fasted for a similar period and in view of the apparently normal glycogen stores and the normal response to glucagon in two of the children in this particular group we are unable to explain the hypoglycaemia

Porte et al (20) have shown low circulating insulin levels following epinephrine infusion High circulating catecholamines have been reported by Barbero & Braddock (1) in cystic fibrosis We considered this a possible reason for the insulinopenia However Handwerger et al (9) found that an infusion of phentolamine given two hours after a GTT caused no change in the insulin level Hence it is unlikely that a raised circulating catecholamines could account for the low insulin/glucagon ratio in these four children Raised glucagon levels have been found in certain states associated with increased metabolic rate such as following burns (27) and trauma (17) Two other conditions associated with high glucagon levels are liver cirrhosis (14) and renal failure (2) but there was no evidence to suggest the presence of either of these two conditions in the cystic fibrosis patients studied here

Analogous results have been described in chronic pancreatitis (12) in association with low insulin response

At the present time we cannot state with certainty the sources of the circulating glucagon which are measuring by radioimmunoassay Our pancreatic glucagon antiserum reacts with the C-Terminal portion of the glucagon molecule and this has been thought to be associated with a pancreatic glucagon specific antiserum This antiserum has low cross reactivity with extracts of gut but recent studies from our laboratory would suggest that there are some materials particularly in the stomach and colon that will cross react with this antiserum (7) In addition studies in dogs have suggested that the proximal gastrointestinal tract contains material very similar to pancreatic glucagon and indeed circulating pancreatic glucagon has been found to rise following pancreatectomy (16 25)

It is therefore possible that the glucagon levels which we are recording in this study especially in the insulinopenia patients are being derived from extra pancreatic sources Unless glucagon radioimmunoassays are modified and improved to recognize this the question will remain unanswered

We can conclude that insulin secretion is depleted in the majority of patients with cystic fibrosis However the conclusions with regard to glucagon secretion must remain guarded Some children do have diminished glucagon secretion but others have apparently

DIMINISHED LIMB BLOOD FLOW IN INFANTS WITH TRANSPOSITION OF THE GREAT VESSELS AN ADAPTATION TO CHRONIC HYPOXIA?

WILLIAM F POWERS and PAUL R SWYER

From th Research Institute of the Hospital for Sick Children and the Department of Pediatrics University of Toronto Toronto Canada

ABSTRACT Powers W F and Swyer P R (Research Institute of the Hospital for Sick Children and the Department of Pediatrics University of Toronto Toronto Canada) Diminished limb blood flow in infants with transposition of the great vessels An adaptation to chronic hypoxia Acta Paediatr Scand 66 205 1977.—Calf blood flow was measured by venous occlusion plethysmography using a mercury in rubber strain gauge in infants with transposition of the great vessels (TGV) and in comparable infants free from cardiopulmonary disease Resting calf blood flow in the infants with TGV was 3 6±0 8 ml/100 ml/min while in the control group flow was 6 8±2 3 ml/100 ml/min a highly significant difference We postulate that newborns with TGV decrease their resting calf flow in response to chronic hypoxia

KEY WORDS Peripheral circulation transposition of the great vessels hypoxia

Despite severe hypoxemia many infants with cyanotic congenital heart disease thrive Apparently tissue hypoxia and anaerobic metabolism are not the inevitable consequences of this severe hypoxemia To avoid hypoxia to critical tissues the infant could decrease his metabolic rate improve his oxygen extraction and/or alter his cardiac output and its distribution We have studied term infants with transposition of the great vessels (TGV) and found that their limb blood flow is lower than normal We report here our results and speculate that the human newborn at least in part copes with chronic hypoxemia by altering his peripheral circulation

MATERIALS AND METHODS

The clinical characteristics of the infants with TGV are given in Table I All were studied within the first week of life and all had undergone a balloon septostomy for [illegible] TGV None had had the Blalock Hanlon operation at the time of the study though four had this procedure later Some were digitalized at the time of study (Table I) but none had received diuretics for at least 24 hours prior to the time of study None were in clinically evident congestive cardiac failure at the time of the blood flow study though two may have been in early failure These two infants are described in Tables I and 3 but not included in statistical analyses All infants were resting quietly No anesthesia or sedatives were used Infants of comparable weight and postnatal age free from significant cardiorespiratory disease when studied were controls (Tables 2 and 4) None were receiving phototherapy at the time of study (20 24) After an explanation of the nature of these studies the parents gave verbal consent that they be carried out

The infants were studied in their incubators in a neutral thermal environment (16) at least two hours after the last feeding (25) Blood flow was measured exclusively in the left leg *for its vessels had* not been manipulated during the prior catheterization and septostomy procedure nor had they sustained arterial or venous punctures One cyanotic infant had had an umbilical arterial catheter in place which had been removed prior to the flow study Our previous work has shown that the prior use of an umbilical arterial catheter does not affect subsequent blood flow to the limb (21)

Blood flow was measured by venous occlusion plethysmography using a mercury in rubber strain gauge as

RESULTS

Calf blood flow (mean±S D) in our control infants was 6 8±2 3 ml/100 ml/min (Table 4) a value similar to those reported previously for well term infants (16 20 22 25) In contrast mean flow in the infants with TGV was 3 6±0 8 ml/100 ml/min (Table 3) This 48% decrease in flow was highly significant t=3 55 p<0 01 Average Pa_{O_2} in the infants with cyanotic heart disease was 26 5±3 3 mmHg significantly different from the mean Pa_{O_2} of 61 0±10 1 mmHg in the control infants t=8 63 p<0 01 Mean birth weight postnatal age pH Pa_{CO_2} pulse and respiratory rate systolic blood pressure and hematocrit were not significantly different in the two groups

DISCUSSION

Celander (7) found that normal newborn infants made acutely hypoxic decreased their peripheral flow He further demonstrated a more pronounced peripheral vasoconstriction in the asphyxiated human neonate (6)

Experimental physiologists have shown that the newborn goat (13) and the mature fetal lamb (1 4 5 8 12 14) similarly respond to acute hypoxemia by decreasing their femoral lower aortic or carcass blood flow while placental cardiac and carotid flow increases Cardiac output remains the same or decreases (4 8 10) Thus teleologically speaking in acute hypoxia the periphery is restricted in order to supply more vital organs so as to

maximize the benefit from a compromised global oxygen supply This adjustment obtains despite constancy of Pa_{CO_2} (8, 11, 13) In the acutely asphyxiated experimental fetus where hypercarbia and acidemia are superimposed upon hypoxia peripheral flow is even further decreased (1, 8 11 18)

We believe that the diminished peripheral flow which we have documented in newborn infants with TGV represents their adaptation to chronic hypoxia and parallels the hypoxia induced circulatory changes seen acutely in newborn humans and experimental animals

The conditions under which our patients were studied do not explain the decrease in peripheral flow which we have observed for factors such as temperature (2 16) interval since feeding (25) phototherapy (20 24) age and birth weight (6 16) were carefully controlled The reduced flow in infants with TGV is not due to an increased hematocrit for the hematocrits of the two groups were comparable and differences in true hematocrit that might be attributed to sampling methods at this age are probably insufficient to explain viscosity changes large enough to account for the observed reduction in flow (3 19)

Since all the cyanotic infants we studied had only one lesion TGV it is possible that the observed flow reduction is explained by some circulatory peculiarity of TGV For instance it is theoretically possible that in TGV because of the impediment to mixing of the pulmonary and systemic circuits the systemic circulation is underfilled in comparison to the pulmonary circuit The frequent finding of pulmonary plethora in infants with TGV is consistent with this hypothesis Thus the systemic hypoperfusion we have measured would be explained not by hypoxia but by systemic hypovolemia We do not believe that this particular mechanisms was operating for the two infants who might have been in marginal failure at the time of study (Patients E and H in Table 1) would have been most likely to have had an overloaded pulmonary circuit and a depleted systemic circuit Hence their systemic peripheral flows should have been but indeed were not lower than the rest

Moreover Corpus & Hait (9) measured limb blood flow in older children with a different cyanotic lesion Tetralogy of Fallot and found that in these chronically hypoxic patients peripheral flow was also reduced Thus since acute hypoxia decreases lower body circulation in fetal and neonatal animals since the human neonate responds to acute hypoxia by peripheral vasoconstriction and since older children with other cyanotic heart lesions show diminished peripheral circulation we believe that chronic hypoxia is the most plausible explanation for the decrease in peripheral flow which we have demonstrated in newborns with TGV

maximize the benefit from a compromised global oxygen supply This adjustment obtains despite constancy of Pa_{CO_2} (8 11 13) In the acutely asphyxiated experimental fetus, where hypercarbia and acidemia are superimposed upon hypoxia peripheral flow is even further decreased (1 8, 11 18)

We believe that the diminished peripheral flow which we have documented in newborn infants with TGV represents their adaptation to chronic hypoxia and parallels the hypoxia induced circulatory changes seen acutely in newborn humans and experimental animals

The conditions under which our patients were studied do not explain the decrease in peripheral flow which we have observed for factors such as temperature (2 16) interval since feeding (25) phototherapy (20 24) age and birth weight (6 16) were carefully controlled The reduced flow in infants with TGV is not due to an increased hematocrit for the hematocrits of the two groups were comparable and differences in true hematocrit that might be attributed to sampling methods at this age are probably insufficient to explain viscosity changes large enough to account for the observed reduction in flow (3 19)

Since all the cyanotic infants we studied had only one lesion TGV it is possible that the observed flow reduction is explained by some circulatory peculiarity of TGV For instance it is theoretically possible that in TGV because of the impediment to mixing of the pulmonary and systemic circuits the systemic circulation is underfilled in comparison to the pulmonary circuit The frequent finding of pulmonary plethora in infants with TGV is consistent with this hypothesis Thus the systemic hypoperfusion we have measured would be explained not by hypoxia but by systemic hypovolemia We do not believe that this particular mechanisms was operating for the two infants who might have been in marginal failure at the time of study (Patients E and H in Table 1) would have been most likely to have had an overloaded pulmonary circuit and a depleted systemic circuit Hence their systemic peripheral flows should have been but indeed were not lower than the rest

Moreover Corpus & Hait (9) measured limb blood flow in older children with a different cyanotic lesion Tetralogy of Fallot and found that in these chronically hypoxic patients peripheral flow was also reduced Thus since acute hypoxia decreases lower body circulation in fetal and neonatal animals since the human neonate responds to acute hypoxia by peripheral vasoconstriction and since older children with other cyanotic heart lesions show diminished peripheral circulation we *believe that chronic hypoxia is the most plausible* explanation for the decrease in peripheral flow which we have demonstrated in newborns with TGV

TRANSFER FACTOR IN CHRONIC AND RECURRENT RESPIRATORY TRACT INFECTIONS IN CHILDREN

P GRÖHN

From the Institute of Biomedical Sciences School of Medicine University of Tampere and from the Children s Department Tampere Central Hospital Tampere Finland

ABSTRACT Grohn P (The Institute of Biomedical Sciences School of Medicine University of Tampere and the Children s Department Tampere Central Hospital Tampere Finland) Transfer factor in chronic and recurrent respiratory tract infections in children Acta Paediatr Scand 66 211 1977.—Five cases with abnormal sensitivity to respiratory tract in fections are described The cases showed a marked impairment in their cell mediated im munity state Administration of a chromatographically purified transfer factor component increased the skin test sensitivity to common recall antigens Interestingly a similar effect in skin reactivity was observed with repeated skin tests alone when antigen concentrations initially high enough to cause a positive reaction were used Neither the administration of transfer factor nor skin testing with high antigen concentrations had an effect on blast trans formation percentages The therapy with chromatographically purified transfer factor appeared promising on the clinical condition of the patients

KEY WORDS Transfer factor cellular immunity respiratory infections

Chronic or recurrent respiratory infections including episodes of tonsillitis otitis sinus itis bronchitis and pneumonitis are frequent ly seen in pediatric patients Occasionally specific causes such as defects in the granulo cyte function or in humoral immune response can be demonstrated but only in a minority of the whole patient group In some patients a specific or a nonspecific disturbance in the cellular immunity may be responsible for the impaired resistance to infection

Human dialyzable transfer factor (dTF) described by Lawrence was claimed to induce delayed hypersensitivity to recipients having a negative skin reactivity before the transfer (8) Despite the lack of clear knowledge of the biological mechanism of TF activity dTF has successfully been used as a therapeutic agent in a variety of conditions with decreased re sistance to infections (3)

Our group has fractionated dTF by gel filtra tion chromatography with Sephadex G 10 and found that the major activity was present in a fraction designed VIa and eluting character istically late from the column This chromato graphically purified TF was subsequently used in successful therapeutic trials in cases of juvenile rheumatoid arthritis miliary lupus of the face and in chronic urinary tract infections (4 5 1)

The present work deals with the state of cellular immune response in a group of chil dren suffering from repeated respiratory infec tions without a demonstrable defect in their antibody synthesis and with normal granulo cyte function tests In most of these patients skin testing revealed a decreased delayed hypersensitivity to common recall antigens such as tuberculin and oidiomycin and thera peutic trial with fraction VIa from dTF had a beneficial effect

The present work deals with the state of cellular immune response in a group of children suffering from repeated respiratory infections without a demonstrable defect in their antibody synthesis and with normal granulocyte function tests In most of these patients skin testing revealed a decreased delayed hypersensitivity to common recall antigens such as tuberculin and oidiomycin and therapeutic trial with fraction VIa from dTF had a beneficial effect

MATERIALS AND METHODS

Description of the patients

Five children with an increased sensitivity to respiratory tract infections were included in this report (Table 1)

Table 1 *Description of the patients and transfer factor therapy*

Patient	Sex	Age (y)	Diagnosis	Number of injections	Follow up time (mo)
1	F	6	Bronchitis chr *Prurigo Besnier* *Alopecia totalis*	9	19
2	M	12	Bronchitis chr tonsillitis residivans	4	17
3	M	4	Bronchitis chr *Otitis residivans* Atrophia cerebri cum epilepsiam	15	19
4	M	2	Bronchitis residivans Candidiasis unguis	8	18
5	M	2	Bronchitis residivans Tonsillitis residivans	10	18

Investigations which were performed in order to find a possible cause for their sensitivity to infections revealed *normal levels in lymphocyte and granulocyte counts* as well as normal granulocyte function evaluated with the NBT test and normal levels of immunoglobulins and complement components C1 C3 and C4 in each case T and B cell levels and tests to evaluate the phagocytosis function of blood monocytes had not been performed

Controls

The skin test sensitivity in healthy children was estimated in 15 cases and the blast responses to PHA PPD and OM in 7 cases These results have been reported earlier (4) The booster effect of repeated skin testing on skin reactivity was evaluated in 5 cases of juvenile rheumatoid arthritis (JRA) 3 cases with recurrent respiratory tract infections (RI) and 9 cases with urinary tract infections (UTI) Two control groups (A and B) were formed Initially the highest concentration of PPD needed for a positive skin reaction was estimated in both groups similarly to the patient group Patients in group A received PPD at the highest concentration which still gave a negative reaction in the initial test while the patients in group B also received the concentration which gave a positive reaction initially (Table 2)

Purification of dTF

Human leucocyte dialyzates derived from pooled buffy coat cells obtained from healthy blood donors (The Finnish Red Cross Transfusion Service Helsinki Finland) were fractionated on a Sephadex G 10 column as previously described (6) Fraction VIa eluting after the total volume of the column

$$K_d = \frac{V - V}{V_t - V} = 1\ 68$$

was pooled lyophilized and weighed

It was redissolved in physiological saline at a concentration of 15µg/ml and sterilized with Millipore filtration Aliquots of 1 0 ml volume were stored at −20 C for further use

Skin testing

Skin testing was performed by using tuberculin (PPD State Bacteriological Laboratory Copenhagen Denmark) and oidiomycin (OM) Dermatophytin O Hollister Stier Spokane WA USA) PPD was used in concentrations of 0 1 TU 1 TU 10 TU and 100 TU and OM in dilutions of 1 500 and 1 50 The skin testing was started with weak concentrations and repeated at one week intervals until either a positive reaction was noticed or the highest concentration of the test antigen was used The test antigen was injected at a dose of 0 1 ml on volar sites of upper arms and the results were registered after 24 48 and 72 hours An erythema and induration of more than 5×5 mm in diameter was regarded as a positive reaction Grading of skin tests in presented in Table 2

Lymphocyte stimulation

Phytohemagglutinin (PHA Phytohemagglutinin P Difco Laboratories Detroit Mich USA) PPD and OM were used as antigens The blast transformation test was performed by a method described earlier (6) Leucocytes 2×10[6] separated by Ficoll Isopaque gradient were cultured in plastic dishes in RPMI 1640 medium (Orion Helsinki Finland) containing 20% Fetal Calf Serum (Flow Laboratories Irvine Scotland) Cell were harvested after three days (PHA) and six days (PPD OM) and cell preparations were made by Shandon cytocentrifuge for May Grunwald-Giemsa staining The percentage of blasts from all lymphoid cells was estimated with the aid of an ocular grid

General plan of the study

Before the administration of fraction VIa the in vivo reactivity to PPD and OM was evaluated by skin testing and the in vitro reactivity to these antigen and PHA by the blast transformation method Together with the first

injection of fraction VIa the skin testing was repeated with the concentrations which had given negative responses initially The effect of fraction VIa on lymphocyte stimulation was registered for a week later Occasionally both the in vivo and in vitro tests were repeated during the trial Injections of fraction VIa were given at the beginning of the trial once a week two times and thereafter once or twice a month for 5 to 1? months The evaluation of the therapy was done by registering the infectious episodes and the need of antimicrobial therapy during and after the trial

RESULTS

The effect of fraction VIa on skin testing

Before the administration of fraction VIa cases 1 and 2 showed skin test anergy to PPD while patients 3 and 4 were skin test positive to 100 TU and case 5 to 10 TU of PPD Testing with OM showed that only case 2 had a positive reaction After the injection of fraction VIa the skin test reactions were markedly strengthened in all cases with PPD and three cases with OM (Table 3)

The effect of fraction VIa on lymphocyte stimulation

Blastogenic responses to PPD were of medium strength in cases 3 4 and 5 Generally administration of fraction VIa did not alter the patients in vitro reactivity in lymphocyte stimulation tests Responses to PHA were within normal limits before and after TF therapy and threre was equally no significant change in the responses to PPD or OM in spite of a clear increase in skin reactivity to the same antigens (Table 3)

Control groups

In healthy children the mean skin test sensitivity to PPD was between 1 and 10 TU and to OM between dilutions 1 500 and 1 50 (Table 3 Fig 1) The mean blast transformation responses were 82 1 to PHA 3 2% to PPD and 1 4% to OM (Table 3) Repetition of skin tests caused a significant increase in con

trol group B, where is only one case in control group A had an increased reactivity after the repeated skin testing (Table 2.)

The clinical effects of fraction VIa

Case 1, a girl, suffered from recurrent bronchitis which began a few months after her birth in November 1968. At the age of three years she had an eruption of an atopic exzema which she has had ever since. Simultaneously she lost her hair as well as eyelashes and eyebrows. The exzema was not treated topically or systemically. Her living conditions were standard before, during and after the trial. She received 9 injections of fraction VIa during a 10 month period, starting in September 1974. During this time she had only one episode of infection and during the nine months follow-up period, since the discontinuation of the injections, she had only one attack of otitis, not requiring antibiotics. Her eyelashes, eyebrows and hair have started to grow, and she no longer needs to wear a wig. The treatment had no effect on the atopic exzema (Table 1).

Case 2, a boy, had had chronic bronchitis beginning a month after his birth in June 1962. In addition, he had recurrent tonsillitis and during the last two years before the start of TF trial, he needed antibiotics either for bronchitis or tonsillitis on the average of once every other month. He received 4 injections of fraction VIa during six months, starting in November 1974. During that period and also the subsequent year, he has not had a single infection requiring antibiotics, but has only encountered influenza A during the epidemic in February 1976 (Table 1).

Case 3, a boy, had had repeated upper respiratory tract infections starting a few month after his birth in October 1970. In 1972 a biopsy from the bronchial mucous membrane showed changes indicating chronic bronchitis. He has had epileptic attacks from the age of two years and a pneumoencephalogram showed cerebral atrophy. The therapeutical trial with fraction VIa was started in September 1974 and he received 12 injections during 13 months. During that time he had three episodes of bronchitis, which was considerably less than before the therapy. However, four months after the discontinuation of the therapy he developed otitis and at this time his skin tests to 100 TU of PPD and 1:50

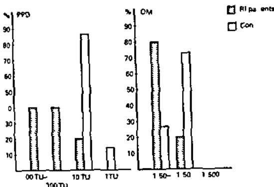

Fig 1 Percentile distribution of PPD and OM skin test values in control material and chronic or recurrent respiratory tract infections (*RI*) of children

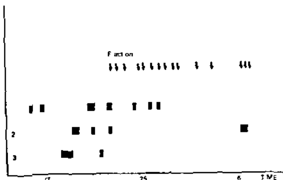

Fig 2 Case 3 Clinical history and the effect of transfer factor therapy (1=bronchitis 2=otitis 3=pneumonia)

dilution of OM were negative A new therapeutical trial has now been started with this case (Table 1 Fig 2)

Case 4 a boy had had recurrent bronchitis beginning a few months after his birth in March 1973 He had candidiasis in his nails since birth and a mild atopic exzema He had frequent otitis and on one occasion this was combined with Bell s paresis He received 8 injections of fraction VIa from October 1974 to July 1975 Since the beginning of this therapy he has had no respiratory infections and the candida has disappeared During the subsequent nine month period after therapy he has been free from symptoms However he did develop a lymphadenitis in his groin after a vaccination against polio (Table 1)

Case 5 a boy was born in September 1972 Since birth he had had attacks of bronchitis almost monthly In addition he had chronic laryngitis with constant *hoarseness* He received 10 injections of fraction VIa from October 1974 to September 1975 There were no respiratory infections during this period but on one occasion he had tonsillitis After the discontinuation of the therapy he had one episode of a common cold (Table 1 Fig 3)

DISCUSSION

The five cases selected to this preliminary trial on the effect of transfer factor on recurrent or chronic respiratory tract infections form a group with an exceptionally grave clinical history They all had recurrent episodes of infections beginning a few months after birth In four of the cases there was only one infectious episode requiring antibiotics during the trial or during the subsequent 9–12 months follow up period In view of the frequency of these episodes before the trial the effect of transfer factor therapy in these cases must be evaluated as promising The living conditions of the patients were considered constant before during and after the therapy as well as these periods included all the seasons of the year

The mechanism of action of TF in these cases as well as in general is however unknown TF was originally described as an informational molecule capable in transferring specific immunological information and it has

Fig 3 Case 5 Clinical history and the effect of transfer factor therapy (1=laryngitis 2=bronchitis 3=tonsillitis)

suggested to be composed of a polynucleotide polypeptide structure (8) Subsequent studies have shown that leucocyte dialyzates contain several functional substances and it is probable that some if not all of the transfer factor s activity is based on a nonspecific stimulatory mechanism (2) In the present study a highly purified TF preparation was used in which the presence of nucleotides or peptides has not been demonstrated Chemical studies on the composition of fraction VIa have revealed that its major component is uracil (7) In addition fraction VIa contains several unidentified small heterocyclic aromatic compounds (6)

Although the defect leading to impaired resistance to infections in these five cases is not known they all seemed to have a decreased cellular immune reactivity as defined by skin testing to recall antigens such as PPD and OM They do not demonstrate defects in humoral immunity and their complement levels were normal Also there was no defect in the granulocyte level or function A positive skin test to a recall antigen is a result of two events a specific one requiring functionally capable sensitized T cells and a nonspecific one expressed by monocytes and macrophages and mediated by lymphokines secreted by the stimulated T cells The fact that the in vitro tests for lymphocyte function were normal in some of the patients in spite of a weak skin reaction to PPD and that there was no alteration in the blastogenic responses of lymphocytes after the administration of fraction VIa even when the skin reactivity increased significantly would indicate that the responding cells in these patients were monocytes rather than lymphocytes It has been previously suggested that the action of TF is based on its effect on monocytes and the present results are in accordance to that view

It is of interest to note that repetition of skin testing caused a strengthening in skin test reactivity when skin testing was repeated in some patients with an antigen dose high enough to cause a positive skin reaction initially After repeated positive skin reactions the patients were observed to react positively to a lower antigen dose It is still unclear whether this observation is based simply on an immunogenic effect of the test antigen or whether the liberation of biologically active substances from the lymphocytes at the site of skin reaction might have more general effects and stimulate the whole monocyte population of the body Repetition of skin tests can either decrease or increase skin test sensitivity This has been shown to depend on antigen dose site of repetition interval of repetition and number of antigen doses (9) The way with which skin testing has been performed in this study excludes the possibility of the repeated skin tests to affect skin reactivity

ACKNOWLEDGEMENTS

This study has been supported by grants from The Sigrid Jusélius Foundation The Emil Aaltonen Foundation and from The State Medical Council of Finland

The generosity of The Finnish Red Cross Transfusion Service in providing us with buffy coat cells is greatly appreciated

TRANSFER FACTOR AND CELLULAR IMMUNE RESPONSE IN URINARY TRACT INFECTIONS IN CHILDREN

R ANTTILA P GROHN and K KROHN

From the Institute of Biomedical Sciences School of Medicine University of Tampere and from the Children s Department Tampere Central Hospital Tampere Finland

ABSTRACT Anttila R Grohn P and Krohn K (The Institute of Biomedical Sciences School of Medicine University of Tampere and the Children s Department Tampere Central Hospital Tampere Finland) Transfer factor and cellular immune response in urinary tract infections in children Acta Paediatr Scand 66 219 1977 —Cellular immune responses in vivo and in vitro were studied in 20 children with chronic or relapsing urinary tract infections Skin tests revealed decreased immune responses to PPD in cases with chronic or recurrent pyelonephritis and to OM in these cases and in cases of lower urinary tract infections Blast transformation responses to PPD OM and PHA were at least as high as in controls Administration of chromatographically purified fraction from human leucocyte transfer factor resulted in a positive skin reaction with antigen concentration which before TF administration had caused a negative reaction The results suggest that the action of the transfer factor component used in this study is based on an immunologically nonspecific stimulation of the cellular immune response

KEY WORDS Transfer factor cellular immunity urinary tract infections

Urinary tract infections (UTI) form a major problem in pediatric practice partly because of their frequency (10) but especially because of their tendency to relapse (2) Several reasons for a susceptibility to recurrent or chronic UTI have been suggested but the reflux phenomenon and anatomical factors such as obstructive malformations or duplications are generally believed to be of greatest importance However other factors may operate in this condition as UTI are often seen in patients without any demonstrable anatomical defects In female patients the tendency to UTI often seems to be familial Also patients with minor or even gross malformation in the urinary tract do not always have a greater tendency for UTI

Immunological defects in recurrent or chronic UTI patients have been looked for but on most occasions they have normal serum immunoglobulin and complement levels as well as granulocyte function test and count in the peripheral blood (7)

The present study was undertaken to find out whether children with different forms of UTI would show impairment in their cellular immune reactivity Secondly we wanted to test the effect of dialyzable transfer factor (dTF) on the immune response We have previously purified a component from dTF and shown that it had promising therapeutic effect in cases with recurrent respiratory infections juvenile rheumatoid arthritis and miliary lupus of the face (3 4 5)

The present study shows that some of the patients with UTI have a decreased cellular immune reactivity and that this reactivity can be increased with chromatographically purified dTF (dTFc)

MATERIALS AND METHODS

Selection of the patients

The material consists of 0 children (1 boy 19 girls) aged from 7 to 14 years with the mean age being 8 1 years All of the patients had suffered from recurrent or chronic urinary tract infections but none of them had an acute episode of the UTI or any other infection at the

time of examination The patients were divided in three groups according to the following criteria

Group I consisted of 5 patients with chronic pyelonephritis (CPN) These patients had had episodes of acute pyelonephritis and they had changes in intravenous pyelography (IVP) and decreased renal function or pathological renal biopsy None of the patients were uremic

Group II had 6 patients with recurrent episodes of acute pyelonephritis (RPN) The diagnosis of acute pyelonephritis (APN) was based on fever micturition disturbances increased erythrocyte sedimentation rate (ESR) positive CRP positive blood culture and increased antibody titer to E coli antigen The urinary findings included proteinuria haematuria pyuria and a bacterial count of more than 10^5/ml in three voided urine specimens or in one urine sample taken with catheter or bladder puncture Transient decreased concentration capacity was also seen in the acute phase

Group III consisted of 11 patients with recurrent lower urinary tract infections (LUTI) These patients had pyuria They had a bacterial count of more than 10^5/ml in three voided urine specimens or in one urine sample taken with catheter or bladder puncture They had disturbances in micturition but neither fever increased ESR CRP nor other findings used for the diagnosis of acute pyelonephritis A description of the patients is given in Table 1

Controls

The in vivo reactivity to PPD and OM was tested in 15 healthy children (mean age 6 2 years) and the in vitro reactivity to PHA PPD and OM in 7 healthy children (mean age 6 0 years) The results have been described earlier (4)

Preparation of the chromatographically purified TF component

Leucocytes from buffy coats (from The Finnish Red Cross Transfusion Service Helsinki Finland) were used as a source of dTF The preparation of dTF has been described earlier (8) Shortly dTF was fractionated on a Sephadex G 10 column by using distilled water as eluent and the active fraction VIa eluting in the outer volume of the columns was collected This was freeze-dried diluted in physiological saline filtered through a 0 22 Millipore filter and used in subcutaneous doses of 15 μg/ml for systemic transfer

Skin testing

Skin tests were performed at weekly intervals with tuberculin (PPD State Bacteriological Laboratory Copenhagen Denmark) in concentrations of 0 1 TU 1 TU 10 TU and 100 TU of PPD and with oidiomycin (OM Dermatophytin O Hollister Stier Laboratories Spokane Wa USA) in dilutions of 1 500 and 1 50 On the first occasion the two weakest concentrations of PPD and OM were used In cases with negative PPD reactions 10 TU of PPD was given for a week later followed by *100 TU in those cases which were negative to 10 TU* The results were registered after 24 48 and 72 hours *An erythema and induration of more than* 5×5 mm in diameter was regarded as a positive reaction Grading of the skin test results was as follows PPD 0 1 TU+=4 1 TU+=3 10 TU+=2 100 TU+=1 and 100 TU−=0 OM 1 500+=2 1 50+=1 and 1 50−=0 Statistical evaluation was performed by using Student s *t* test

Lymphocyte stimulation

Cell cultures were made according to the method described earlier (8) 20 ml of venous blood was drawn into a heparinized plastic syringe Leucocytes were *separated by Ficoll Isopaque gradient and* 2×10⁶ cells were cultured in plastic dishes with RPMI 1640 (Orion Helsinki Finland) and 20% Foetal Calf Serum (Flow Laboratories Irvine Scotland) as the medium Phytohemagglutinin (PHA Phytohemagglutinin P Difco Laboratories Detroit Mich USA) PPD and OM were used as antigens Harvesting was made after three days (PHA) and six days (PPD OM) Cell preparations were made by Shandon cytocentrifuge for May Grunwald Giemsa staining The percentage of *blasts from all* lymphoid cells was counted with the aid of an ocular

grad The percentages in cultures without antigen were subtracted from the percentages in cultures with antigen

Course of the study

On the first occasion the lymphocyte cultures were taken and the skin testing was started One week after the last skin tests were made the effect of dTFc was estimated by injecting a single dose of 15 µg of dTFc subcutaneously and by repeating the highest skin test concentration which gave a negative response initially The lymphocyte cultures were repeated a week later

RESULTS

The state of cellular immunity of the patients

Decreased blast transformation responses to PHA were seen only in cases 2 and 7 The mean blast percentages of PHA differed significantly from the control material but were in normal ranges The blast percentages of PPD and OM showed no significant differences to the control material (Table 3)

The mean skin test value to PPD was 1 0 in group I 1 7 in group II and 2 0 in group III (for grading see methods) The mean value for all the groups was 1 6 Reactivity to PPD differed significantly from the control material in patient group I The responses to OM were 0 2 0 5 0 2 and 0 3 in groups I II III and in all of the groups respectively A significant difference to controls was seen in patient groups I III and the total test groups (Table 2) The percentile distribution of the skin test results of the patients and the controls is presented in Fig 1

The effect of dTFc

Blast transformation After the administration of dTFc an increase in blast percentages was

observed in some individual cases This was seen especially with PPD in the most anergic patients in group I However in the whole material or even in the different groups as a whole the blast percentages to PPD and OM before and after the administration of dTFc did not significantly differ (Table 3)

Skin testing Administration of dTFc caused a clear strengthening of the skin test responses The mean skin test values after the transfer (2 5 to PPD and 0 5 to OM) differed significantly from the values before the transfer but did not differ from the values of the control group

DISCUSSION

Cellular immune reactivity in children suffering from different forms of urinary tract infections was studied by skin testing and by in vitro blast transformation tests The patients series was divided into three groups according to severity of the disease Impaired reactivity by skin testing was observed in all three groups particularly in groups I and II with chronic or relapsing pyelonephritis This observation was especially clear with PPD as the antigen while the candida antigen oidiomycin did not clearly differentiate the patient group from the controls As all of the patients in the present series have been vaccinated with BCG we feel that PPD is an especially suitable antigen In controls significant differences were not noticed in skin test values to PPD or OM in various age groups Contrary to the skin testing the blast transformation tests were not abnormal in the patients Only two patients had a weak PHA response and the blast percentages with PPD were in fact higher with patients than with controls A positive skin reaction requires both the antigen specific reactivity of the target cells such as blood monocytes to the mediators secreted by the stimulated lymphocytes Thus skin testing covers a wider range of reactivities than the in vitro blast transformation test

A chromatographically purified fraction of human dialyzable transfer factor dTFc was used in this study to correct the impaired cellular immune reactivity The results were similar to those observed earlier by us in patients with generalized sarcoidosis juvenile rheumatoid arthritis and in chronic or recurrent respiratory tract infections in children One injection of dTFc virtually normalized the skin reactivity to PPD whereas no alteration was seen in the blast transformation test This kind of dissociation in cell mediated immune response after transfer factor therapy has been reported previously by many authors (1 6 9)

Our results suggest that the failure in cellular immune reactivity in the patients is not in the capacity of lymphocytes to recognize and respond to the antigen but either in the lymphokine secretion or in the reactivity of target cells to the lymphokines A similar situation has previously been observed with uremic patients but none of the cases in the present series had uremia Also none of the patients had signs of acute infection and the drugs received by the patients are not known to cause immunosuppression One may therefore conclude that the observed decreased cellular immune reactivity was not the result of the disease and could thus be of etiological significance for the process

The present results suggest that some of the children with chronic or relapsing urinary tract infections do have an impaired cellular immune reactivity and that this can be corrected with transfer factor Whether this observation has any therapeutical implications is currently under investigation

ACKNOWLEDGEMENTS

This study has been supported by grants from The Sigrid Jusélius Foundation The Emil Aaltonen Foundation and from the State Medical Council of Finland

The generosity of The Finnish Red Cross Transfusion Service in providing us with buffy coat cells is greatly appreciated

NEONATAL SEPTIC OSTEO ARTHRITIS DUE TO UMBILICAL ARTERY CATHETERISATION

FINN URSIN KNUDSEN and STEN PETERSEN

From the Department of Paediatrics Glostrup Hospital Glostrup Denmark

ABSTRACT Knudsen F U and Petersen S (Department of Paediatrics Glostrup Hospital Glostrup Denmark) Neonatal septic osteo-arthritis due to umbilical artery catheterisation Acta Paediatr Scand 66 225 1977.—Three cases of neonatal septic osteo-arthritis due to umbilical artery catheterisation are described The clinical features were characteristic A week after removal of the catheter a septic osteo-arthritis developed The etiological agent in all three cases was Staphylococcus aureus resistant to penicillin The disease is probably caused by haematogenous spread of septic clots from thrombus formation on the catheter Symptoms and signs were few and vague It is suggested that septic osteo-arthritis due to umbilical catheterisation is more frequent than hitherto believed and low-grade forms might remain undiagnosed

KEY WORDS Newborn umbilical artery catheter septic osteo-arthritis osteomyelitis

Septic osteo arthritis seems to be a rare complication of umbilical artery catheterisation as only a single case has been reported previously (12) It has not been mentioned in surveys dealing with neonatal septic osteo arthritis and osteomyelitis (1 2 6 9 11) or in papers surveying the complications of umbilical artery catheterisation (3 4 8 10) Septic osteo arthritis in the newborn may be silent but resulting disablement is common (6 9 11)

MATERIALS

During the years 1974–76 3 cases of septic osteo-arthritis in infants below the age of 1 month were diagnosed A total of 60 umbilical artery catheterisations were performed during this period (2½ years) One of the following diagnostic criteria was fulfilled 1) existence of pus in the joint involved and growth of pathogenic bacteria or 2) existence of sterile pus in the joint but radiological signs of osteomyelitis in the metaphysis Table I presents the clinical findings in the 3 cases The clinical pictures were almost identical Pregnancy and birth were uncomplicated Because of IRDS (idiopathic respiratory distress syndrome) an umbilical artery catheter was inserted at the age of 4 hours in all 3 cases The following aseptic technique was observed The umbilical cord and the surrounding skin was cleansed twice with 2 5% iodine in alcohol The tincture was allowed to dry between the two applications The umbilical cord was cut 1 cm above the skin level and the catheter was inserted Sterile gloves sterile self adhering surgical drape and local application of 1% hexachlorophene powder were used Systemic or local antibiotic treatment was not given The umbilicus was covered by an appropriate sterile dressing and adhesive tape Following our experiences we later altered our technique to that used in surgical operative procedures with gown cap and mask The position of the catheter tip in the aorta on the level of the second lumbar vertebra was controlled by X ray Catheterisation lasted 3–7 days The first symptoms of osteo arthritis were noticed 3–10 days after removal of the catheter According to the literature skin infections or purulent rhinitis are frequent before septic osteo-arthritis (9) but this was not seen in our cases The first patient had a pleural tube inserted for 3 days because of pneumothorax the second and third patients were not exposed to procedures predisposing to infection other than umbilical artery catheterisation None was intubated for RDS The symptoms of osteo-arthritis were only local reduced mobility and tenderness of the involved leg which was kept in flexion In cases 1 and 2 there were no redness or swelling of the hip In case 3 there was swelling and warmth of the knee but no visible signs that the hip or ankle were affected 2 infants had no fever at all 1 had fever for one day All had high erythrocyte sedimentation rate (31–87 mm/h) and leucocytosis (18 000–25 000/μl) with a majority of neutrophils (48–73%)

Table 1 *Clinical and bacteriological findings in 3 cases of neonatal septic osteo arthritis*

Case no	Sex	Birth weight (g)	Clinical findings: Clinical diagnosis	Catheter inserted/ removed (day of life)	Arthritis symptoms (day of life)	Joints involved	Bacteriological findings: Catheter	Blood	Pus from joint
1	F	2 800	IRDS	2–7	14	Left hip	Staph aureus	No growth	No growth
2	F	2 500	IRDS	2–9	19	Left hip	Staph aureus	Not done	Staph aureus
3	M	3 000	IRDS	2–5	8	Right hip Left knee Right ankle	Not done	Staph aureus	Staph aureus

Antibiotics given for 1 day before joint puncture

Radiological findings At the time when the osteo arthritis was diagnosed X ray disclosed nothing abnormal in the 3 cases Two weeks later osteolytic processes in the metaphysis developed in cases 1 and 3 Case 2 developed lateral displacement of the femur but without signs of osteomyelitis In case 3 osteolytic processes developed in the distal metaphysis of the tibia without swelling or reduced mobility

Treatment The 3 patients were treated with joint puncture aspiration of pus immobilisation and lincomycin for 3–4 weeks The course was uncomplicated Signs and symptoms subsided and at a follow up 3–16 months later there were no clinical signs of sequelae X rays were normal

RESULTS

The bacteriological findings are presented in Table 1 In case 1 penicillin resistant Staphylococcus aureus was found on the catheter tip but there was no growth in pus from the hip joint after 1 day s antibiotic treatment In case 2 penicillin resistant Staphylococcus aureus phage type 3 A was found on the catheter tip and 19 days later in the joint In case 3 the catheter tip was not examined but blood culture and pus from hip and knee joints disclosed penicillin resistant Staphylococcus aureus with an identical pattern of resistance Phage typing was not done

DISCUSSION

The similar clinical features of the 3 cases strongly suggested a correlation between umbilical artery catheterisation and septic osteo arthritis After removal of the catheter the neonates had no signs or symptoms at all for 3 to 10 days, after which septic osteo arthritis developed The delay of local signs probably indicated that the haematogenous spread of infection from septic thrombosis was particularly related to the removal of the catheter It should be stressed that one of our patients showed Staphylococcus aureus phage type 3 A on the tip of the catheter and the same phage type was cultured 3 weeks later from plus aspirated from the hip joint

Neonatal septic osteo arthritis is generally caused by bacterial spread i e septic embolisation or transitory bacteraemia (2) Multiple bone or joint involvement often occurs (2) In neonates the disorder characteristically affects the metaphysis of long bones with a preference for the humerus and the femur (2 6) When umbilical catheterisation is involved the hip joint and the upper metaphysis of the femur seemed to be the most frequent localisation The inability of the metaphysis to handle infection is probably due to the sluggishness of the bloodstream and the non anastomosing small arteries in this area in which septic clots are readily captured In neonates however the infection can rapidly spread to the epiphysis Furthermore it has been pointed out that the joint capsule encloses the metaphysis of the hip joint which facilitates spread of infection to the joint (6) The distinction between septic

osteo arthritis septic arthritis and septic osteomyelitis is essential from a prognostic point of view The prognosis seems to be correlated to the age of the infant and the site and spread of the infection Lindblad et al (6) found that marked residual disability among children with acute haematogenous osteomyelitis was almost exclusively restricted to newborn infants with a complicating purulent osteo-arthritis of the knee or hip joint Radiological signs of osteomyelitis are often delayed In our cases we found a clinical picture of septic arthritis initially which later showed evidence of osteomyelitis in the metaphysis We have therefore called this condition septic osteo-arthritis We cannot exclude the possibility of a primary osteomyelitis in the metaphysis or epiphysis with spread to the joints

The majority of newborn infants have no significant surface bacterial colonization immediately after delivery Over the first days of life the skin and the umbilicus show a steady increase in numbers of bacteria It has been suggested that the umbilicus becomes colonized more quickly and perhaps more heavily than other parts of the skin There is thus a possibility that contamination of the catheter is more likely when catheterisation is performed at a later stage which may increase the risk of systemic infection

As demonstrated by aortography 95% of infants with umbilical artery catheters had distinct thrombus formation in the aorta (7) In several cases asymptomatic arterial clots in iliac and femoral arteries were found About 50% of indwelling umbilical catheters were contaminated with pathogenic or non pathogenic organisms (5) Therefore it seems reasonable to presume that septic embolism is a frequent occurrence It cannot be excluded that asymptomatic self limiting or low grade septic osteo arthritis due to umbilical catheters is a common event One of our patients demonstrated a septic osteo-arthritis without signs or symptoms and a silent but radiographically verified osteomyelitis

Table 1 *Clinical and bacteriological findings in 3 cases of neonatal septic osteo arthritis*

			Clinical findings				Bacteriological findings		
Case no	Sex	Birth weight (g)	Clinical diagnosis	Catheter inserted/removed (day of life)	Arthritis symptoms (day of life)	Joints involved	Catheter	Blood	Pus from joint
1	F	2 800	IRDS	2–7	14	Left hip	Staph aureus	No growth	No growth
2	F	2 500	IRDS	2–9	19	Left hip	Staph aureus	Not done	Staph aureus
3	M	3 000	IRDS	2–5	8	Right hip, Left knee, Right ankle	Not done	Staph aureus	Staph aureus

Antibiotics given for 1 day before joint puncture

Radiological findings At the time when the osteo arthritis was diagnosed X ray disclosed nothing abnormal in the 3 cases Two weeks later osteolytic processes in the metaphysis developed in cases 1 and 3 Case 2 developed lateral displacement of the femur but without signs of osteomyelitis In case 3 osteolytic processes developed in the distal metaphysis of the tibia without swelling or re duced mobility

Treatment The 3 patients were treated with joint punc ture aspiration of pus immobilisation and lincomycin for 3–4 weeks The course was uncomplicated Signs and symptoms subsided and at a follow up 3–16 months later there were no clinical signs of sequelae X rays were normal

RESULTS

The bacteriological findings are presented in Table 1 In case 1 penicillin resistant Staphy lococcus aureus was found on the catheter tip but there was no growth in pus from the hip joint after 1 day s antibiotic treatment In case 2 penicillin resistant Staphylococcus aureus phage type 3 A was found on the catheter tip and 19 days later in the joint In case 3 the catheter tip was not examined but blood cul ture and pus from hip and knee joints disclosed penicillin resistant Staphylococcus aureus with an identical pattern of resistance Phage typing was not done

DISCUSSION

The similar clinical features of the 3 cases strongly suggested a correlation between um bilical artery catheterisation and septic osteo arthritis After removal of the catheter the neonates had no signs or symptoms at all for 3 to 10 days after which septic osteo arthritis developed The delay of local signs probably indicated that the haematogenous spread of in fection from septic thrombosis was particular ly related to the removal of the catheter It should be stressed that one of our patients showed Staphylococcus aureus phage type 3 A on the tip of the catheter and the same phage type was cultured 3 weeks later from plus aspirated from the hip joint

Neonatal septic osteo arthritis is generally caused by bacterial spread i e septic emboli sation or transitory bacteraemia (2) Multiple bone or joint involvement often occurs (2) In neonates the disorder characteristically affects the metaphysis of long bones with a pref erence for the humerus and the femur (2 6) When umbilical catheterisation is involved the hip joint and the upper metaphysis of the femur seemed to be the most frequent localisa tion The inability of the metaphysis to handle infection is probably due to the sluggishness of the bloodstream and the non anastomosing small arteries in this area in which septic clots are readily captured In neonates however the infection can rapidly spread to the epiphysis Furthermore it has been pointed out that the joint capsule encloses the metaphysis of the hip joint which facilitates spread of infection to the joint (6) The distinction between septic

ANTIMICROBIAL FACTORS IN HUMAN MILK

VINODINI REDDY C BHASKARAM N RAGHURAMULU and V JAGADEESAN

From the National Institute of Nutrition Indian Council of Medical Research Jamai Osmania Hyderabad India

ABSTRACT Vinodini Reddy Bhaskaram C Raghuramulu N and Jagadeesan V (National Institute of Nutrition Hyderabad India) Antimicrobial factors in human milk Acta Paediatr Scand 66 229 1977.—Levels of Immunoglobulins lactoferrin and lysozyme were determined in milk samples obtained from well nourished and under nourished Indian women at different stages of lactation The concentration of immunoglobulins and lactoferrin was higher in colostrum than in mature milk while the lysozyme levels showed a progressive increase with the period of lactation There were no significant differences in the levels between the two groups of women Administration of iron did not alter either the total or percentage saturation of lactoferrin in milk These results indicate that antibacterial factors in milk are not influenced by the nutritional status of the mother and that iron supplementation does not interfere with the bacteriostatic function of lactoferrin

KEY WORDS Lactoferrin Immunoglobulins lysozyme

It is well known that the incidence of infections in bottle fed infants is higher than that in breast fed infants (9) Apart from increased bacterial contamination during bottle feeding this difference has been attributed to the presence of various antibacterial factors in breast milk such as immunoglobulins lysozyme and lactoferrin There is however little information regarding the changes in the concentration of these factors with the period of lactation and also whether the nutritional status of the mother modifies these levels We therefore decided to obtain such information

In vitro studies have shown that saturation of lactoferrin with iron abolishes its bacteriostatic activity This raises an important question as to whether supplementation of iron to the mother can alter the saturation of lactoferrin in milk and thus interfere with its biological function We have carried out studies to investigate this possibility

MATERIAL AND METHODS

Samples of breast milk were collected from 250 women at various stages of lactation The women were classified into two groups based on weight/height² index This index has been shown to reflect nutritional status (8) Women with an index of 0 18 or more were considered well nourished and those below 0 18 as undernourished Body weights ranged from 40–55 kg in the well nourished and 34–39 kg in the undernourished group Most of the well nourished women belonged to the high socio-economic group and were attending a private nursing home while the undernourished women belonged to the low socio-economic group and were attending the general hospital

Milk samples were analysed for IgA IgG IgM lactoferrin and lysozyme Immunoglobulins and lactoferrin were determined by the radial immunodiffusion technique (4) Purified colostral IgA and its specific antiserum were obtained from W H O reference centre for immunoglobulins and used for the estimation of IgA levels in milk The antiserum is specific for the secretory component of the molecule Lysozyme content of milk was determined by the method of Parry et al (11) Haemoglobin was determined by the oxyhaemoglobin method and serum albumin by the Biuret method

Eleven lactating women were given 200 mg of iron intramuscularly Milk samples were collected initially and

one month after administration of iron Saturated lactoferrin was determined by the method described by Bullen et al (2)

RESULTS

The results are shown in Tables 1 2 and Figs 1 and 2 The concentration of IgA was high in colostrum the mean level being 350 mg/100 ml and showed a rapid fall during the first 4 weeks of lactation reaching a mean level of 110 mg/100 ml in mature milk IgM showed a similar pattern The concentration of IgG was slightly higher in colostrum than in mature milk There were no significant changes in the levels of immunoglobulins during the subsequent stages of lactation

The concentration of lactoferrin was very high in colostrum the mean level being 600 mg/100 ml and showed a progressive fall up to 5 months of lactation and then stabilised at a mean level of 180 mg/100 ml Lysozyme content of colostrum was lower than that of mature milk and showed a progressive increase with the duration of lactation reaching the highest level of 42 mg/100 ml at 12 months

There were no significant differences in the levels of immunoglobulins lactoferrin and lysozyme between well nourished and under nourished women (Table 1) Also there was no correlation between these factors on the one hand and either Haemoglobin or serum albumin levels on the other

In women who received iron supplements initially the mean level of total lactoferrin was 240 mg/100 ml 9 0% of which was saturated There were no significant changes in the concentration of either total or saturated lactoferrin after administration of iron (Table 2)

Table 2 *Effect of iron therapy on lactoferrin in milk*
Values are means ±S E of 11 subjects

	Total lactoferrin (mg/100 ml)	Saturated lactoferrin (% of total)
Before iron therapy	240±29 0	9 0±7 15
After iron therapy	260±80 0	8 6±3 32

DISCUSSION

There are several clinical and epidemiological observations to suggest that breast milk has a protective role against infection in the infant Enteric infections due to *E coli* and *Shigella* are rare in breast fed infants unlike in artificially fed babies (5 7) Even in developing areas where exposure to various enteropathogenic organisms is common diarrhoeal disease is uncommon in breast fed babies

during early infancy and appears only with weaning (9) It is now recognized that there are many antibacterial factors in human milk which may be responsible for its protective function

Milk contains different classes of immunoglobulins such as IgG IgM IgA etc Of these IgA which is characteristic of bodily secre tions is the predominant immunoglobulin in human milk (6) Secretory IgA with antibody activity against many types of micro-organ isms confers local immunity in the gastro-intestinal tract of the infant The concentration of IgA is high in colostrum and shows a drop in the first week of lactational period But the increase in milk production may then com pensate for the fall in immunoglobulin con centration

Human milk also contains large quantities of an ironbinding protein lactoferrin which has a strong bacteriostatic effect (10) Bullen et al have found that saturation with iron abolished the bacteriostatic effect of lactoferrin (2) It has been suggested that iron therapy may interfere with the function of lactoferrin How ever the results presented here indicate that administration of iron to the mother does not alter the saturation of lactoferrin in milk and therefore may not interfere with its bacterio-static function This observation is of con siderable practical importance since iron supplements are currently being given to the

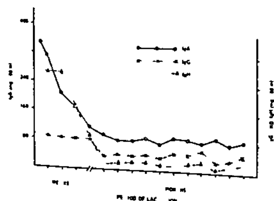

Fig 1 Immunoglobulin levels as mg/100 ml in milk secreted at different periods of lactation

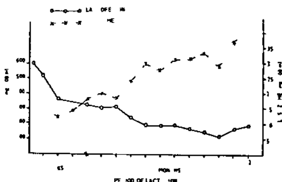

Fig 2 Levels of lactoferrin (O—O) and content of lysozyme (× ×) in milk secreted at different periods of lactation

pregnant and lactating women of poor com munities for the prevention of anaemia

Lysozyme is another antibacterial factor abundant in human milk (3) Its possible in fluence on the faecal flora is suggested by the fact that it is found in significant amounts in the stools of breastfed infants Unlike im munoglobulins and lactoferrin which showed highest concentration in colostrum lysozyme levels showed a progressive increase with the period of lactation Similar changes have been reported earlier in Indian women but not in western women (13 12) The reason for this difference is not clear

The results of the present study indicate that the antibacterial defense factors in milk are not influenced by the nutritional status of the mother This finding is of considerable public health significance since a majority of the women in poor communities are under nour ished These results are in line with the earlier studies reported from this Institute wherein the total protein content of milk samples ob tained from poor Indian women was found to be similar to that of well nourished western women (1)

The data presented here indicate that breast milk contains significant amounts of immuno-globulins lactoferrin and lysozyme even at the end of one year of lactation These qualities of breast milk may be of major importance for the infant s defense against infection par

THE RADIAL DYSPLASIA/IMPERFORATE ANUS/VERTEBRAL ANOMALIES SYNDROME (THE VATER ASSOCIATION) DEVELOPMENTAL ASPECTS AND EYE FINDINGS

B SAY D GREENBERG R HARRIS S L DeLONG
and J G COLDWELL

From the Department of Developmental Medicine & Child Neurology Children s Medical Center Tulsa Oklahoma USA

ABSTRACT Say B Greenberg D Harris R. DeLong S L. and Coldwell J G (Department of Developmental Medicine & Child Neurology Children s Medical Center Tulsa Oklahoma USA) The radial dysplasia/imperforate anus/vertebral anomalies syndrome (the VATER association) developmental aspects and eye findings Acta Paediatr Scand 66 233 1977 —The developmental evaluations of four children of different age groups with radial dysplasia/imperforate anus/vertebral anomalies syndrome are presented These show that although the gross motor behavior is significantly delayed intelligence language and social development are within normal range Therefore the patients with this syndrome merit every effort toward rehabilitation Three of the patients discussed have ophthalmological abnormalities in addition to their major malformations It may be that congenital eye defects are another component of this syndrome of morphogenesis

KEY WORDS Radial dysplasia/imperforate anus/vertebral anomalies syndrome developmental studies eye findings

Since its description in 1968 under the title of polydactyly/imperforate anus/vertebral anomalies syndrome (3) the entity of multiple congenital malformations has been steadily expanded First as was predicted it was shown that the preaxial limb deformity was not always in the form of polydactyly but frequently consisted of hypoplasia or absence of the thumb (8) This was followed by reports indicating that other defects of mesodermal origin such as tracheoesophageal fistula with or without esophageal atresia cardiovascular and renal defects were not uncommon in these patients (4) Later in an attempt to name this condition various acronyms such as VATER association (2) VACTERL (1) etc were proposed which we do not favor for reasons described elsewhere (5) Finally it was suggested that despite the severity of their physical deformities these patients may have normal mental development (6 7) which was of course of great practical importance indicating that the subjects with this syndrome deserve all efforts toward rehabilitation

In this communication we present four new illustrative cases of different age groups confirming the favorable impression of others that children with this syndrome are not necessarily intellectually impaired Additionally we will propose that ophthalmological abnormalities may be another component of this syndrome of dysmorphogenesis

PATIENTS

Case I

G H a 14 month-old black female was the second born of presumably identical twin girls weighing 1125 g at birth while her twin weighed 1800 g The mother was ? years of age and was in good health The pregnancy was essentially uncomplicated except that it terminated

ticularly in developing countries where the risk of infection is high In poor Indian communities fortunately prolonged breast feeding is still the practice This should be encouraged as it has many advantages

the kidneys Although she had a II/VI mild systolic mur mur heard best at the apex the opinion of the cardiologist was that this was most likely a functional murmur Ophthalmologic examination showed her vision to be 20/30 on right and 20/40 on left correcting to 20/30 in each eye with refraction These findings were considered to be within normal range Psychological evaluation using the Stanford Binet Test revealed an I Q of 91 which indicated that the patient had a level of intellectual functioning in the lower end of the average range

Case 4

T N was a 10-year-old white male who at birth was found to have imperforate anus and esophageal atresia associated with tracheoesophageal fistula On the right forearm the radius carpal bones on the radial side as well as first metacarpal bone and the thumb were absent He had multiple deformities of the spine including a fusion of the first and second ribs on the right a hemi vertebra at the T1 and T2 level and spina bifida Also he was found to have a heart murmur possibly due to an ASD Ophthalmologic examination showed ptosis of the left eyelid anisocoria (right pupil larger than the left) and heterochromia iridis

A Wechsler Intelligence Scale for Children (Revised) was administered and his full scale I Q was found to be 100 His verbal I Q however was 109 while the performance I Q was 90

DISCUSSION

Using the Gesell Developmental Examination the adaptive behavior of Cases 1 and 2 appears in the low average or average range However gross motor behavior is significantly delayed and hypotonia appears in both children The third and fourth patients had I Q s well within the normal range and fine and gross motor development appeared adequate in Case 3 while it was slightly impaired in Case 4 It is very important to separate the gross motor delays seen in these youngsters from their adaptive function in order to prevent labeling them as mentally retarded especially in the earlier years and therapeutic efforts must be vigorous Considering the vast arrays of physical anomalies and their need for surgical correction and ongoing therapy every effort must be made to treat these children according to their intellectual levels rather than their motor function Also it is important to avoid making blanket statements regarding such children s ultimate intelligence when they are first evaluated in the neonatal period

Another interesting finding was the fact that three of the four children had unilateral ophthalmological abnormalities which had a tendency to appear in the left side (Table I) Most of the eye findings were of little clinical significance however no mention of ophthalmological findings could be encountered in other published cases This may indicate that such findings in our patients may be coincidental On the other hand one may speculate that the abnormalities related to the eye may have been missed because of their mild nature Future reports on similarly affected patients may shed a light on this aspect

ACKNOWLEDGEMENTS

We thank Dr R F Gates Mr L Warnberg for their assistance in evaluating their patients and Mrs B Barnes for her excellent technical help

at 35 weeks There were two amnions but only one chorion A previous child also was born prematurely weighing 1 600 g The mother denied exposure to drugs or irradiation during the pregnancy The family history was negative for birth defects

The patient was evaluated by us at the age of 6 weeks The spectrum of malformations observed included imperforate anus bilateral inguinal herniae a hypoplastic thumb on right and a left preauricular tag She also had hypoplasia of the left radius and ulna as well as multiple rib anomalies X ray of the spine showed hemivertebrae involving cervical vertebrae and L 1 Butterfly bodies were seen in the cervical and upper dorsal regions Some fusion also was present at the level of D 5 and 6 The heart was globular in shape but no definite abnormalities could be detected IVP showed faint visualization of both kidneys Ophthalmologic findings included ptosis of the left eyelid left internal strabismus and clouding of the left cornea without glaucoma (Table 1) The corneal lesion presented itself initially as a central erosion without edema which healed very poorly over a period of several months leaving a moderately dense corneal nebula No cause for this lesion could be established

She was evaluated using the Gesell Developmental Examination Because she was 5 weeks preterm her corrected age was 13 months The test results revealed an adaptive behavior 48 weeks gross motor behavior 28 weeks fine motor behavior 36 weeks language 40 weeks and personal social behavior 52 weeks Her adaptive behavior at 48 weeks while she was 57 weeks old gave her a developmental quotient of 84% which was in the low average range of intelligence Neurological examination demonstrated generalized hypotonia which was spontaneously improving in a cephalocaudad progression All reflexes appeared to be normal

Case 2

A M was a 15 month old female who was the only child born to a healthy couple The birth weight was 1 530 g The mother was 29 years of age and the father 31 at the time of the patient s birth The pregnancy which lasted 34 weeks was complicated by an episode of spotting about the 7th or 8th week and by massive edema and hypertension (240/150) during the last few weeks No history of exposure to known teratogens could be obtained Specifically she was not on any kind of contraceptive pills for the past 2 years prior to the pregnancy Family history was essentially negative especially with regard to birth defects

The patient s deformities in addition to imperforate anus included tracheoesophageal fistula with esophageal atresia hypoplastic right radius and 13 ribs bilaterally She also had 6 lumbar vertebrae and probable agenesis of the left kidney Ophthalmologic examination showed her right eye to be normal and her left eye −8 diopters myopic

This patient who was 6 weeks preterm considered at 58 weeks corrected age was tested using the Gesell Developmental Examination The results were as follows adaptive behavior 60 weeks gross motor behavior 48 weeks fine motor behavior 60 weeks language 16 months and finally personal social behavior 15 months Developmental quotient=60/58=103 was in the average intelligence range Neurological examination revealed hypotonia in all extremities and trunk which was improving without therapy in a cephalocaudad progression

Case 3

K M was a 5 year old black female born six weeks prematurely weighing 2 040 g Both mother and father were 21 years of age at the time of the patient s birth Exposure to drugs and irradiation during the pregnancy was denied The family history was essentially negative Two sisters of the patient 4 and 7 years of age respectively were reported as being in good health

The spectrum of malformations in the patients included imperforate anus with rectovaginal fistula hemivertebra at D-7 with a fusion of D-10 and D-11 synostosis of the 10th and 11th ribs on left and crossed fused ectopia of

CONTROL OF STREPTOMYCIN AND ISONIAZID IN MALNOURISHED CHILDREN TREATED FOR TUBERCULOSIS

Y AKBANI P BOLME B S LINDBLAD and R J RAHIMTOOLA

From the Paediatric Clinics of Jinnah Postgraduate Medical Centre Karachi Pakistan and St Goran s Children s Hospital Stockholm Sweden

ABSTRACT Akbani Y Bolme P Lindblad B S and Rahimtoola R J (The Paediatric Clinics of Jinnah Postgraduate Medical Centre Karachi Pakistan and St Goran s Children s Hospital Stockholm Sweden) Drug control of streptomycin and isoniazid in malnourished children treated for tuberculosis Acta Paediatr Scand 66 237 1977 —In 12 malnourished children who were treated for tuberculosis plasma levels of streptomycin and isoniazid were followed Streptomycin was administered i m in a dose of 25–50 mg/kg/24 hours High initial plasma levels were reached (mean 44.3 μg/ml at 30 min) Streptomycin levels were followed for 5 hours and the mean plasma level at that time was 17 0 μg/ml From the present data a plasma half life of streptomycin of 3 5 hours has been estimated It is advised that streptomycin should not be given in doses above 25 mg/kg/24 hours to avoid potential toxic plasma levels especially if plasma levels cannot be measured It is also concluded from our study that renal function is not affected in malnourished children to an extent where streptomycin clearance is greatly affected Isoniazid was given orally 10 mg/kg/24 hours From 30 min to 6 hours after administration mean plasma levels of isoniazid above 0 5 μg/ml were observed In all children measurable plasma levels were obtained It is concluded that also children with malnutrition can absorb isoniazid after oral administration From our data it is suggested that the majority of the children in our study were rapid inactivators of isoniazid

KEY WORDS Tuberculosis children malnutrition streptomycin isoniazid

In the developing countries malnutrition is a dominating problem during early childhood Malnourished children seem to have a deficient cellular immune system (3 4 18) which makes them susceptable to several infectious diseases in particular tuberculosis An adequate chemotherapy is therefore critical for a successful treatment of tuberculosis in malnourished children

However in the state of malnutrition it may be difficult to predict the fate of pharmacological agents since drug absorption (8) as well as drug metabolism (15 16) and excretion (1 12) may be different in a malnourished child as compared to a well nourished child A combination of streptomycin and isoniazid is commonly used in the treatment of tuberculosis By studying the pharmacokinetics of isoniazid and streptomycin in malnourished children treated for tuberculosis we intended to gain some knowledge of an adequate dosage in this group of children At present the therapy is based only on studies of well nourished children

MATERIAL AND METHODS

Included in the study are 12 children 5 months–6 years of age admitted to the Pediatric Clinic Jinnah Postgraduate Medical Centre Karachi and treated for tuberculosis with streptomycin and isoniazid The routine treatment during the initial phase of serious tuberculosis was streptomycin sulphate in citrate buffer (pH 5 8–6 1) 25–50 mg i m /kg

---

[1] Natr citrat 14 g natr sulfis 7H O 4 7 g acid citric ca 1 g (pH 5 8–6 1) methylparaoxibenz 1 5 g propylparaoxibenz 0 ? g aqua steril ad 1000 g

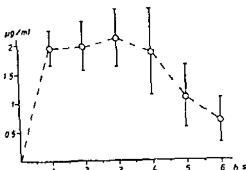

Fig 2 Plasma levels of isoniazid after oral administration of 10 mg/kg of INH to 12 children with malnutrition Means±S E M are shown

tion was almost reached at one hour and was then kept for the next three hours

DISCUSSION

Surprisingly little is known about the pharmacokinetics of streptomycin in well nourished children and nothing at all is studied about this drug in children with malnutrition It is reported that hearing loss can occur in children to mothers treated with streptomycin during pregnancy (5 17) and in adults it is well known that streptomycin can damage the function of the eighth cranial nerve and cause especially vestibular dysfunction (14) Thus vertigo nausea etc might serve as warning signals of too high streptomycin concentrations However in sick children such symptoms may be difficult to notice and therefore the risk of permanent damages to the eighth cranial nerve with loss of hearing and labyrinthine dysfunction are increased In the present study we have not been able to follow those children who survived to test for hearing abnormalities

From the study of Line et al (14) it seems as if high peak levels of streptomycin are to a lower degree associated with side effects than a retarded clearance of the drug This would indicate that patients with decreased renal function are at risk to develop ototoxicity Premature infants are known to have decreased renal function and it has been reported that the plasma half life of streptomycin in premature children was 7 hours compared to adult values of 2 4–2 7 hours (7) The mean plasma half life value in our group of patients was estimated to 3 5 hours and from these results it does not seem as if children with marasmus as a rule have a greatly affected renal function However three of our children of which two had received 50 mg/kg had concentrations of streptomycin at 5 hours exceeding 25 µg/ml (28–39 µg/ml) It would therefore seem important to determine streptomycin plasma levels not only as was done in the present experiments during five hours after the dose but also just before the next dose (i e 24 hours after administration of streptomycin)

It seems advisable from our data to use no more than 25 mg/kg/dose unless streptomycin concentrations can be determined In children with signs of impaired renal function it is necessary to observe possible side effects as nausea vomiting nystagmus etc It is not satisfactory to relay on simple renal tests like creatinine or urea in states of malnutrition since these tests may fall within normal values even when renal function is low

Measurable concentrations of isoniazid were reached in all our patients after oral administration The malnutrition did not seem to affect the gastrointestinal absorption in these marasmic infants

Isoniazid is metabolized in the liver before excretion and the main metabolite is the acetyl derivative There exist at least two populations of people in the ability of metabolizing isoniazid slow and rapid inactivators due to different concentrations of activities of the enzyme (6 11) The proportion of slow/rapid acetylators seem to vary in different ethnical populations (6) From our experiments where the drug was given orally it is not possible to draw definite conclusions about the rate of metabolism of isoniazid since absorption can still continue even though the plasma concentration curve is declining However the relatively rapid drop in plasma concentration from 4 to 6 hours (half life≈90 min) makes it reason

* Mid arm circumference

once daily and isoniazid orally 10 mg/kg once daily Capillary blood samples were taken at several time intervals after drug administration The individual patients are listed in Table 1 All children were in a state of serious malnutrition

For the assay of streptomycin plasma was put on microdiscs 10 µl on each disc usually in triplicates The discs were dried and frozen and were later transported in frozen and dried condition to Stockholm Sweden where the analysis was made

The microbiological agar diffusion method was used for the determination of streptomycin calculated as the base A staphylococcus strain was used in the assay and a freshly prepared standard series was always included when the determinations were done A more detailed description of the method has been published by Jalling et al (9) and Bolme & Eriksson (2)

Plasma was also frozen for the determination of isoniazid and transported to Stockholm The method described by Lever (13) was used for isoniazid assay The method is based on a condensation in aqueous solution of aromatic acid hydrazides and β-diketones to form yellow anions in the presence of a strong base We have modified the method so that 100 µl of plasma was enough for a valid determination of concentrations down to 0 15 µg/ml of free isoniazid

The blood samples were collected during a two month period They were frozen immediately after the tests The assays of streptomycin were performed 3–12 weeks after the sample collections and no decomposition occurs during this time All isoniazid analyses were done during a period of one week 4–6 months after the tests

RESULTS

Fig 1 illustrates the concentrations of streptomycin from 30 min to 5 hours after the administration of streptomycin High initial concentrations were achieved The mean value for the entire material at 30 min was 44 3 µg/ml and the highest individual value was 72 µg/ml (after 50 mg/kg streptomycin) The highest individual value after 25 mg/kg was 52 0 µg/ml Even at 5 hours after streptomycin administration plasma values above what is considered as therapeutic levels (10 µg/ml or more) were achieved the mean value in all children being 17 0 µg/ml An estimation of the plasma half life of streptomycin from the present material gives a value of 3½ hours No acute side effects of streptomycin were noticed

The plasma concentrations of isoniazid after a single oral dose of 10 mg/kg are illustrated in Fig 2 In all patients a measurable plasma concentration was achieved The peak concentra

MENARCHEAL AGE IN GIRLS WITH CONGENITAL DISLOCATION OF THE HIP

N FREDENSBORG and B E NILSSON

From the Department of Orthopedic Surgery University of Lund Malmo General Hospital Malmo Sweden

ABSTRACT Fredensborg N and Nilsson B E (Department of Orthopedic Surgery University of Lund Malmo General Hospital Malmo Sweden) Menarcheal age in girls with congenital dislocation of the hip Acta Paediatr Scand 66 241 1977.—The age at menarche was recorded in a series of girls with congenital dislocation of the hip and compared with a control sample drawn from the population at risk The menarcheal age of the CDH patients was decreased by on average six months the decrease being caused by the presence among the CDH girls of a few individuals with a very early menarche These girls were heavier and taller than other CDH girls who in their turn are taller and heavier than other girls The findings support the concept of CDH as a manifestation of some hormonal deviation which also causes early physical maturation

KEY WORDS Menarche congenital hip dislocation

Andren & Borglin (2 3 4) found that a deviation from normal in the estrogen chemistry may be a factor in the etiology of congenital dislocation of the hip (CDH) Fredensborg (6) attempted to study the influence of this proposed hereditary hormonal factor on the menarche in girls with CDH by comparing their menarcheal age with the data of Andersen (1) However the latter data were not collected during exactly the same time period nor from the same population as the data of the CDH girls It is known that there is a secular trend of a decreasing menarcheal age (7) This secular trend does not seem to have been halted yet in Sweden (8) Also in fairly recent Scandinavian data socio-economic influences on the menarcheal age have been demonstrated (5) Since the difference in menarcheal age between girls with CDH as compared with normal girls cannot be expected to be great it is necessary to obtain controls from the population at risk

MATERIAL AND METHODS

CDH was diagnosed in 3? new born girls between 1956–1961 No cases with combined malformations were included (teratological cases) and in all cases the treatment had resulted in completely normal hip joints The girls were *all* born in the city of Malmö by Swedish parents By the time of the interview all the girls diagnosed during this time period had had their menarche In addition 288 girls from the City of Malmo schools were studied these did not have congenital hip dislocation and were born by Swedish parents in Malmo The control girls were born during the same time period as the CDH sample *With the* aid of the City School Medical Service the girls to be

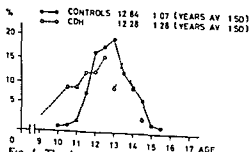

Fig 1 The distribution of menarcheal age in CDH girls and control girls There is a skewedness to the left in the CDH girls

able to assume that the majority of the children were rapid inactivators who are reported to have plasma half lives of 40 to 100 min (10) This was also the impression from the curves of the individual experiments

ACKNOWLEDGEMENTS

We wish to express our thanks to Anette Bister for excellent technical assistance in the determinations of isoniazid and streptomycin The study was supported by grants from the Swedish Medical Research Council (19X 3877) and Svenska Lakarsallskapet (Carin Tryggers fond)

MENARCHEAL AGE IN GIRLS WITH CONGENITAL DISLOCATION OF THE HIP

N FREDENSBORG and B F NILSSON

From the Department of Orthopedic Surgery University of Lund Malmo General Hospital Malmo Sweden

ABSTRACT Fredensborg N and Nilsson B E (Department of Orthopedic Surgery University of Lund Malmo General Hospital Malmo Sweden) Menarcheal age in girls with congenital dislocation of the hip Acta Paediatr Scand 66 241 1977 —The age at menarche was recorded in a series of girls with congenital dislocation of the hip and compared with a control sample drawn from the population at risk The menarcheal age of the CDH patients was decreased by on average six months the decrease being caused by the presence among the CDH girls of a few individuals with a very early menarche These girls were heavier and taller than other CDH girls who in their turn are taller and heavier than other girls The findings support the concept of CDH as a manifestation of some hormonal deviation which also causes early physical maturation

KEY WORDS Menarche congenital hip dislocation

Andren & Borglin (2 3 4) found that a deviation from normal in the estrogen chemistry may be a factor in the etiology of congenital dislocation of the hip (CDH) Fredensborg (6) attempted to study the influence of this proposed hereditary hormonal factor on the menarche in girls with CDH by comparing their menarcheal age with the data of Andersen (1) However the latter data were not collected during exactly the same time period nor from the same population as the data of the CDH girls It is known that there is a secular trend of a decreasing menarcheal age (7) This secular trend does not seem to have been halted yet in Sweden (8) Also in fairly recent Scandinavian data socio-economic influences on the menarcheal age have been demonstrated (5) Since the difference in menarcheal age between girls with CDH as compared with normal girls cannot be expected to be great it is necessary to obtain controls from the population at risk

MATERIAL AND METHODS

CDH was diagnosed in 32 new born girls between 1956–1961 No cases with combined malformations were included (teratological cases) and in all cases the treatment had resulted in completely normal hip joints The girls were all born in the city of Malmo by Swedish parents By the time of the interview all the girls diagnosed during this time period had had their menarche In addition 288 girls from the City of Malmo schools were studied these did not have congenital hip dislocation and were born by Swedish parents *in Malmö* The control girls were born during the same time period as the CDH sample With the aid of the City School Medical Service the girls to be

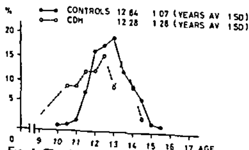

Fig 1 The distribution of menarcheal age in CDH girls and control girls There is a skewedness to the left in the CDH girls

interviewed as controls were selected from several schools to represent a socio-economic cross section of the city All the girls CDH girls and controls were interviewed in the same manner with regard to their age at the time of the first menstrual bleeding

RESULTS

The age at menarche for the 32 girls with CDH was about 6 months less than for the control sample The difference was significant $0.01>p>0.001$ (t test of samples of unequal size) (Fig 1) The distribution of menarcheal age in the control sample demonstrated in the figure hardly deviates from normal there may be a slight tendency to skewedness to the right In the CDH sample, however there is a skewedness to the left, whereas the modal values for the two sets do not differ significantly This seems to indicate the presence among the CDH cases of a small number of girls with an exceedingly early menarche

The seven CDH girls who were 11 or less at the time of menarche were compared with the total sample of CDH girls diagnosed in the years 1956–1964 (6) In four of the seven girls there was at least one additional case of CDH in the family as compared with 7% in the total sample (98 girls) Heights and weights were available in six of the seven girls In all instances the heights and the weights were above average for CDH girls

DISCUSSION

In the control sample which was drawn in order to match the CDH cases rather than to describe the distribution of menarcheal age in Malmo there exists a certain bias owing to the presence among the youngest girls interviewed of a few who had not yet attained their menarche Since the number is small and taking into account the previously known age distributions of menarcheal age, this fact could at most deduct 0 1 year from the real average menarcheal age It is possible to draw the conclusion that at present the average menarcheal age in the city of Malmo is less than 13 which supports the concept of a continuing secular trend of decrease

The findings of the present study support the hypothesis of a hormonal influence in CDH Additional support for this hypothesis are the findings of Fredensborg (6) of a somewhat increased height and weight in young girls who had been born with CDH as compared with a control sample In the present study those girls who had the lowest menarcheal age deviated even more being taller and heavier than not only control girls but also other CDH girls Both factors menarche and body size reflect an early physical maturation

ACKNOWLEDGEMENTS

Financial support was obtained from the Swedish Medical Research Council (project no B76-17X 2737-08A) and from the Herman Jarnhardt Foundation Olof Smitt M D Chief School Physician helped with the collection of the control samples

HERPES ENCEPHALITIS

B WOLMAN and M LONGSON

From the Department of Paediatrics and North Manchester Regional Virus Laboratory Booth Hall Children s Hospital Manchester England

ABSTRACT Wolman B and Longson M (Department of Paediatrics and North Manchester Regional Virus Laboratory Booth Hall Children s Hospital Manchester England) Herpes encephalitis Acta Paediatr Scand 66 243 1977.—Four cases of herpes encephalitis treated with dexamethasone and cytarabine Cases were all verified by brain biopsy and immunofluorescent techniques Attention is called to the need for early diagnosis but the difficulty of deciding when to perform brain biopsy is discussed Early treatment with effective drugs is necessary to prevent permanent brain damage

KEY WORDS Herpes encephalitis brain biopsy treatment long term brain damage

It has been estimated that up to 50 cases of herpes encephalitis are diagnosed each year in the United Kingdom (8) but that perhaps as many as 150 cases are unrecognized Although it has been suggested (9 12) that mild herpes encephalitis with a good prognosis can occur many have argued (8) that the overall mortality is as high as 60% There is a grave danger of neurological crippling in survivors (10) We report the cases of four children who have survived but whose mental condition is severely affected

CASE REPORTS

Case 1

K B a female was admitted to hospital on 7 April 1974 aged years 9 months with a one week history of a bad cold with nasal discharge Four days before admission she had started with fits initially rightsided becoming progressively more severe and generalized On the day of admission she became confused and disorientated There were no significant neurological features on examination The CSF showed 64 leucocytes mainly polymorphs per mm but the chemistry was normal and no organisms were seen on the stained slide or obtained on culture The Mantoux test was negative An EEG originally showed bilateral high amplitude delta activity throughout maximal in the left frontal region Two days later the record changed showing periodic high delta waves on a relatively flat background The fits continued despite paraldehyde and diazepam—the girl remaining unconscious A diagnosis of encephalitis was made but as there was no improvement in the next few days a brain biopsy was performed on 11 April 1974 The immunofluorescent test for herpes simplex antigens was positive and eventually *Herpesvirus simplex* was isolated on tissue culture The child was treated with cytosine arabinoside 10 mg per kg daily intravenously for five days and also given dexamethasone 1 mg per kg load followed by ? mg 6-hourly for four days Convulsions continued from time to time The child required diazepam and chlorpromazine to control the fits for the next four months but they eventually stopped and treatment was discontinued She has remained in the same vegetative state with spastic quadriplegia requiring feeding and total care by the parents now twelve months after the illness

Case 2

S K a boy was admitted on 16 August 1974 aged 13 years 10 months with a history of dizziness and diarrhoea starting on 0 July This settled after three or four days but on 10 August he was feverish dizzy and he vomited four times He became progressively drowsy and confused with visual hallucinations but no fits He had been given penicillin for four days of these days by his general practitioner On admission he was confused unable to co-operate showing no specific clinical abnormalities The CSF showed 66 leucocytes 70% of which were polymorphs No other abnormalities were noted in

the CSF and no organisms were seen on the stained slide or obtained on culture A viral encephalitis was diagnosed The EEG showed diffuse slow wave activity most prominent over the left hemisphere particularly in the left temporal region On 17 August brain biopsy was performed *Herpesvirus simplex* antigens were detected by immunofluorescent tests and the virus was eventually isolated on tissue culture He was treated with cytosine arabinoside 10 mg per kg daily intravenously for five days and dexamethasone 10 mg per kg load followed by 10 mg 6-hourly for four more days Treatment was started the day after admission but probably at least seven days after the onset of the illness and maintained for five days Convulsions started on the day after admission and he became unconscious Despite sedation with diazepam and paraldehyde convulsions occurred from time to time and he required tube feeding His condition remained stationary till December 1974 but in January 1975 he gradually regained consciousness stopped convulsing and over the ensuing months he has become more interested in his surroundings although speech has not returned and he cannot stand or walk He will not talk although he does seem to understand a great deal of what is said to him His admission to a Junior Training Centre may be possible

Case 3

A R a female was admitted to another hospital on 24 January 1975 aged 7 months having had a generalized convulsion after a six hour history of crying refusing feeds and vomiting On admission she was unconscious with mainly left sided convulsive movements and weakness of the left arm Examination of the CSF showed 75 cells per mm^3 equally polymorphs and leucocytes Protein was slightly raised but no organisms were seen on the stained slide or obtained on culture A bacterial or viral meningitis was considered and treatment was started with intravenous ampicillin The Mantoux test was negative For 48 hours the convulsions recurred The child remained semi conscious and febrile On 26 January she seemed to improve became conscious and afebrile but the following day the convulsions recurred On 28 January she was transferred to this hospital in a semi conscious state showing convulsive movements of the left side with hemiparesis An EEG showed generalized hyperexcitability mainly in the left temporal region with secondary subcortical activity The diagnosis of herpes encephalitis was suspected A brain biopsy was done and *Herpesvirus simplex* antigens were detected by immunofluorescent tests and the virus itself was later isolated on tissue culture Treatment with cytosine arabinoside 10 mg per kg daily was given intravenously for five days and dexamethasone was given as a 1 mg per kg load followed by 2 mg 6-hourly for four days The convulsions were controlled with diazepam and phenytoin By mid February her condition was unchanged she had occasional convulsive movements was semi conscious and was unable to suck or swallow She had another episode of status on 1 March after which she developed a spastic quadriplegia sucking and swallowing with difficulty Over the past three months her condition has remained unchanged she takes no interest in her surroundings and she screams when disturbed Long term management is difficult because of domestic and social problems

Case 4

M J W a female was admitted to hospital on 22 November 1974 aged 9 months with a history of two weeks vague ill health being fretful and miserable On the day of admission she had a right sided fit and was found to have a right paresis and looked obviously ill There were no other signs The CSF showed 18 white cells 14 of which were lymphocytes with a normal chemistry Bacterial examination was negative and the presumptive diagnosis was viral meningitis with the possibility of a space occupying lesion The baby was observed for four days during which there was slow but obvious deterioration with increasing fits and wildly oscillating temperature and conjugate left deviation of the eyes On 26 November 1974 the EEG showed widespread abnormality with slow wave activity A brain scan on the same day revealed two areas of abnormal uptake of isotope (over vertex and over left occiput) On the following day the carotid angiogram produced a remarkable picture of venous blushing with a profusion of new vessel formation in the left parietal and temporal regions A clinical diagnosis of herpes encephalitis was now queried and a brain biopsy obtained from the affected parietal area The specimen yielded *Herpesvirus simplex* by immunofluorescence and culture The infant was treated with dexamethasone 4 mg intramuscularly initially and 2 mg intramuscularly every 6 hours thereafter and with cytosine arabinoside 100 mg intravenously daily by single bolus injection for five days Initially there was no improvement in her condition but a fortnight after starting the anti viral drug the patient began to improve and over the next twelve months appeared to become more and more interested in her family

Subsequent neuro-psychological assessment of the child has however revealed that she has been left with a most severe disability Now twelve months after her illness she is a severely retarded child and is unable to communicate Using the Griffiths Mental Development Scale she shows a comparatively high loco-motor profile but displays poor performance scores There is nothing in her play activity to suggest a normal development and although she has regained a substantial degree of physical function she has not kept up her cognitive ability to act purposefully

DISCUSSION

These four children illustrate the different and bizarre ways in which herpes encephalitis can present The clinical diagnosis of encephalitis is always difficult When the infection is with *Herpesvirus simplex* the presentation seems to be more varied with fits vomiting diarrhoea

paresis of the cranial nerves clouding of consciousness and variation of severity over a period of several days

The clinician cannot make the diagnosis unaided CSF changes are non specific The EEG may show gross changes but even these are not diagnostic although high wave complexes against a background of diffuse slowing particularly in the temporal lobes has been claimed as a special feature Immunofluorescent demonstration of viral antigens in brain biopsy specimens is now a reliable test giving a result within 1–3 hours from receipt of the specimen but this implies brain biopsy which also may yield the virus on culture within 24–48 hours

The problem therefore seems to be one of deciding when to carry out a brain biopsy in a suggestive case Many children who have repeated convulsions with fits for 24–48 hours settle subsequently without trouble Brain biopsy is certainly not the first investigation to be considered In the cases here reported four days after admission to this hospital (5–12 days after the onset of disease) two days after admission to hospital (8 days after onset) four days after admission (5 days after onset) and four days after admission (about 2½ weeks after onset) were the times before brain biopsy was done Is therefore a period of three or four days before brain biopsy is considered the earliest possible time one can accept?

There is no doubt that the mortality of the disease can be influenced by treatment (3 5 11) but the form which this treatment should take is a matter of dispute

Herpes encephalitis in its severe form causes a disastrous progressive necrosis of the brain It is reasonable to suggest that treatment whatever form it may take can only be effective if it is applied as early as possible during the destructive process

There is clinical and neuropathological evidence (3 4 6) that patients die from cerebral oedema If specific virus chemotherapy is to be effective this oedema must be controlled at all costs and there must be aggressive cerebral decompression This decompression may be achieved surgically or medically with steroids (such as dexamethasone) Most authorities now appear to be agreed that dexamethasone should be administered in high doses in all cases of herpes encephalitis but it remains controversial whether the steroid should be covered by the simultaneous administration of an anti viral drug In the case of herpes encephalitis there are three specifically antiherpes drugs in use—idoxuridine cytarabine and vidarabine

The use of idoxuridine has now been discontinued because of substantial toxicity and failure to prevent death (2) Vidarabine is a relatively new anti viral drug which is currently undergoing clinical assessment in the United States and which has been the subject of preliminary and optimistic reports

Cytarabine is like idoxuridine and vidarabine potently active against the replication of *Herpesvirus simplex* experimentally in cell culture Preliminary promising reports concerning its use come from the Herpes Encephalitis Working Party (7) which should report in 1976 or early 1977 A disquieting feature of the use of cytarabine is the severe neurological damage found in survivors

Previous authors have frequently commented that survival from herpes encephalitis may be associated with severe damage to the brain In view of the pathological process involved and of the intense disruption of nervous tissue which is known to occur this is not surprising The destructive process should be interrupted at a very early stage Earlier diagnosis and earlier exhibition of dexamethasone and cytarabine might improve the prognosis However in our case No 3 both diagnosis and treatment were established on the 5th day of illness and it is difficult to see how this can be improved upon It could also be argued that an invasive diagnostic approach involving brain biopsy might lead to an increased incidence of neurological sequelae but brain biopsy in competent hands is a safe procedure The temporal lobe is the site usually used

the CSF and no organisms were seen on the stained slide or obtained on culture A viral encephalitis was diagnosed The EEG showed diffuse slow wave activity most prominent over the left hemisphere particularly in the left temporal region On 17 August brain biopsy was performed *Herpesvirus simplex* antigens were detected by immunofluorescent tests and the virus was eventually isolated on tissue culture He was treated with cytosine arabinoside 10 mg per kg daily intravenously for five days and dexamethasone 10 mg per kg load followed by 10 mg 6-hourly for four more days Treatment was started the day after admission but probably at least seven days after the onset of the illness and maintained for five days Convulsions started on the day after admission and he became unconscious Despite sedation with diazepam and paraldehyde convulsions occurred from time to time and he required tube feeding His condition remained stationary till December 1974 but in January 1975 he gradually regained consciousness stopped convulsing and over the ensuing months he has become more interested in his surroundings although speech has not returned and he cannot stand or walk He will not talk although he does seem to understand a great deal of what is said to him His admission to a Junior Training Centre may be possible

LEARNING DISORDERS

Some Medical Aspects

NEIL GORDON

From the Royal Manchester Children s Hospital
and Booth Hall Children s Hospital Manchester England

ABSTRACT Gordon N (The Royal Manchester Children s Hospital and Booth Hall Children s Hospital Manchester England) Learning disorders—some medical aspects Acta Paediatr Scand 66 247 1977.—The first skills are motor ones and these depend on perceptual development and the organisation of movement If development is deviant the child will be clumsy The clinical picture is considered and the effects this may have in the school situation Disorders of language development may be secondary to other factors such as deafness or brain injury or may be a specific disability The various grades of the latter are described Both perceptual and language disorders can underlie reading retardation and the analysis of a particular child s difficulties is stressed The etiology of these conditions is discussed with particular reference to the failure of integration Intracerebral connections may not form be destroyed or not used The role of the Doctor is an important one and this includes not only diagnosis and assessment but also helping the child in the home and school especially when emotional and behaviour complications occur The doctor must also act as a questioner and co-ordinator

KEY WORDS Perceptual-motor disorders disorders of language development reading retardation etiology the role of the doctor

Learning disorders are common and there must be few people who can honestly say they have not had some difficulties of this kind In Britain over six per cent of 7 to 8 year old children appear to have a very significant de gree of perceptual motor handicap (3) and 1 6 per cent of boys and 0 8 per cent of girls aged 7 have almost unintelligible speech soon after starting school (14)

PERCEPTUAL MOTOR DISORDERS—CLUMSY CHILDREN

Among the first skills to be learnt are motor ones These depend on the appreciation of shape and sizes the relationship of parts to the whole the orientation of objects and other aspects of perception If these are difficult to learn movements will be clumsy and motor skills difficult to acquire If the disability persists as the child grows older reading and writing will be affected If it is hard for the child to interpret the shape of a triangle this will also apply to letter shapes and will delay the ability to read at least for a while

Some clumsy children will apparently have no particular troubles with perception but cannot easily organise their movements Any one when acquiring a new skill will be clumsy until they practise and build up a repertoire of memory of movements and if an instrument is involved until this is part of the body image It

CONCLUSION

We report four cases of proven herpes en cephalitis all treated with cytarabine who survived the disease We are however severely disquietened by the sequelae and we wonder whether anti viral drugs in herpes encephalitis may be encouraging the survival rate at the price of producing severe neurological cripples

In these four children the poor results of treatment of this disease may be due to irreversible brain damage occurring before the diagnosis is made or to the failure of drugs currently available If diagnosis cannot be achieved earlier then we are entirely reliant on effective drugs in the management of a case at any stage of the illness

ACKNOWLEDGEMENTS

Our thanks are due to Dr M J Noronha for allowing us to include case 4 and to Dr C M P Bradstreet of the Standards Laboratory London for the supply of reagents used in the diagnosis of our patients We also acknowledge the very competent technical assistance provided by Mr A S Bailey F I M L T

ABSTRACT Gordon N (The Royal Manchester Children s Hospital and Booth Hall Children s Hospital Manchester England) Learning disorders—some medical aspects. Acta Paediatr Scand 66 247 1977.—The first skills are motor ones and these depend on perceptual development and the organisation of movement If development is deviant the child will be clumsy The clinical picture is considered and the effects this may have in the school situation Disorders of language development may be secondary to other factors such as deafness or brain injury or may be a specific disability The various grades of the latter are described Both perceptual and language disorders can underlie reading retardation and the analysis of a particular child s difficulties is stressed The etiology of these conditions is discussed with particular reference to the failure of integration Intracerebral connections may not form be destroyed or not used The role of the Doctor is an important one and this includes not only diagnosis and assessment but also helping the child in the home and school especially when emotional and behaviour complications occur The doctor must also act as a questioner and co-ordinator

KEY WORDS Perceptual-motor disorders disorders of language development reading retardation etiology the role of the doctor

Learning disorders are common and there must be few people who can honestly say they have not had some difficulties of this kind In Britain over six per cent of 7 to 8 year old children appear to have a very significant degree of perceptual motor handicap (3) and 1 6 per cent of boys and 0 8 per cent of girls aged 7 have almost unintelligible speech soon after starting school (14)

PERCEPTUAL MOTOR DISORDERS—CLUMSY CHILDREN

Among the first skills to be learnt are motor ones These depend on the appreciation of shape and sizes the relationship of parts to the whole the orientation of objects and other aspects of perception If these are difficult to learn movements will be clumsy and motor skills difficult to acquire If the disability persists as the child grows older reading and writing will be affected If it is hard for the child to interpret the shape of a triangle this will also apply to letter shapes and will delay the ability to read at least for a while

Some clumsy children will apparently have no particular troubles with perception but cannot easily organise their movements Any one when acquiring a new skill will be clumsy until they practise and build up a repertoire of memory of movements and if an instrument is involved until this is part of the body image It

is this process that some children seem to find particularly difficult Studies on acquired cerebral lesions suggest that right hemisphere lesions are *likely* to cause perceptual dis abilities and left hemisphere lesions defects of motor organisation (2) When it comes to therapy distinctions of this kind are important Those with predominantly perceptual dis abilities will need to have the task broken down into component parts and demonstrated, with full use being made of the child s verbal ability It is always easier to discriminate if you describe the task in words If the defect is in motor organisation presumably the solution does lie in continual *practice, suitably moti* vated

Children with perceptual motor disabilities seem to be fairly numerous As has been mentioned, (3) about 6% of 7 to 8 year old children have difficulties of these kinds which means *1 to 2 such children in* each class of 30 to 40 If their difficulties are not recognised they can easily be accused of not trying when in fact they have been doing so to a greater extent than the average Then it is not surprising that they develop secondary emotional disturbances Their difficulties will not only be in the classroom because of illegible writing and so on but these are likely to involve out of class activities as well They are often poor at games and no one wants them in their team or to go on holiday with them Over activity and poor concentration are often associated with inco ordination of this kind and if such school difficulties arise the child is likely to become depressed and to withdraw from the situation

Unless the disability is very marked it may not cause particular comment or put the child under pressure before school entry Also for the majority of these children progress at school will most probably be satisfactory if they can be given a certain amount of help and understanding and above all, credit for their efforts which will have to be greater than aver age So much of the teaching that takes place in the good infant class is just what these children need Therefore, with few exceptions the best time to screen children for this disabil ity may be at school entry or soon afterwards Then the teacher can be alerted to the possibil ity of a child s difficulties and encouragement of efforts and a certain amount of special help may be all that is required There will be some children who are so severely affected that they will need to be educated in a special class or even a special school for example a school for physically handicapped children

DISORDERS OF LANGUAGE DE VELOPMENT

Acquiring one s mother tongue may not be thought of as a learnt skill It is true that the brain has in the words of the linguists the propensities to enable it to extract from the linguistic input the relevant data needed to organise *language into a consistent system* but the same concept could be applied to many other skills (12) There can be no doubt that environment will affect the richness and com plexity of language and the ability to express one s feelings and ideas These statements ap ply to the normal child and if there are specific difficulties in language development the need for teaching language is even more evident

The acquisition of speech and language may be delayed as the result of a variety of dis abilities some of which can be treated It may be possible to compensate for environmental factors for example in preventing some of the deprivation suffered by mentally and physi cally handicapped children A child with se vere cerebral palsy will live in a very restricted world perhaps consisting of one or two rooms at home and the classroom at school There will be few opportunities of exploring the world and experimenting in order to build up the concepts on which so much of inner lan guage depends It has been shown that the way parents talk to their mentally handicapped child can be over simplified and deprive them of the wider experience of language on which

children depend to increase their vocabulary (4) Handicapped children must have the world brought to them if they cannot explore it themselves and must be given the opportunity for new experiences to the limit of their capacities

Deaf child plus hearing aid does not equal normal child Children with severe peripheral deafness as their only handicap still have dif ficulties with abstract thought even if success fully treated from an early age Presumably this is related to the faulty auditory input and the difficulty in explaining to such children ideas rather than facts

Severe emotional disturbances in early life can affect language development but in the case of autism the very abnormal behaviour pattern is most probably the result rather than the cause of the severe disorder of language function The basic problem for these children may be a profound difficulty in using symboli sation of any kind (16)

Acquired disorders of language develop- ment in childhood present special problems at least if the child is affected before the age of ten Not only will there be the results of the damage to the brain in terms of loss of func tion but also an interference with the continu ing development of language function This is well illustrated in Charles Dickens account of Laura Bridgman whom he met in 1842 (10) It is a very entertaining account of how she was helped after becoming blind and deaf and it emphasises that spoken language is the final stage of this development and the importance of what occurs before the child uses words If she had not begun to use words before her illness it is most unlikely that she would have accomplished what she did It may help par ents to realise this and that the first word a child says with meaning is the beginning of the last stage of language development It emphasises the importance of speaking to a child in as meaningful a situation as possible without asking much in return for long periods of time

When the development of language function appears to be delayed to a much greater degree than other aspects of development and in the absence of secondary causes such as those discussed it can be regarded as a specific dis order As with any such disorder the majority will be mildly affected but as Peckham (14) has shown speech and language disorders are fre quent enough among children in Britain start ing school The speech of 14 4 % of boys and 9 7% of girls is not fully intelligible at school entry and to stress this again among 1 8% of boys and 0 9% of girls at this time most of their words are unintelligible

The majority of children with specific dis orders of language development as with any other disability will improve and if given a certain amount of help and understanding in their early years will overcome their disabili ty if they have average intelligence As the severity of the disability increases sounds other than those of language may lack mean ing and the term congenital auditory im perception has been used to describe such children Although fortunately rare the audi tory agnosia can be even more profound and then the child may not respond to sounds of any kind and the abnormal auditory response thought to be due to peripheral deafness The diagnosis may be particularly difficult because a number of causes such as anoxia at birth may damage the auditory nucleus in the brain stem as well as causing more widespread brain damage and central and peripheral deafness may co-exist

Even when the auditory agnosia is severe the abnormal response can alter as the child grows older The child will begin to react to sound and this may be the result of the neces sary associations being made between differ ent parts of the cortex so that meaning can be given to the electrical stimuli coming from the peripheral auditory receptors a theme which will be considered later on

Although the majority of children with specific disorders of language development can be helped within the normal school some times in a special class with the teacher and

is this process that some children seem to find particularly difficult Studies on acquired cerebral lesions suggest that right hemisphere lesions are likely to cause perceptual disabilities and left hemisphere lesions defects of motor organisation (2) When it comes to therapy distinctions of this kind are important Those with predominantly perceptual dis abilities will need to have the task broken down into component parts and demonstrated with full use being made of the child s verbal ability It is always easier to discriminate if you describe the task in words If the defect is in motor organisation presumably the solution does lie in continual practice suitably moti vated

Children with perceptual motor disabilities seem to be fairly numerous As has been mentioned, (3) about 6% of 7 to 8 year old children have difficulties of these kinds which means 1 to 2 such children in each class of 30 to 40 If their difficulties are not recognised they can easily be accused of not trying when in fact they have been doing so to a greater extent than the average Then it is not sur prising that they develop secondary emotional disturbances Their difficulties will not only be in the classroom because of illegible writing and so on but these are likely to involve out of class activities as well They are often poor at games and no one wants them in their team or to go on holiday with them Over activity and poor concentration are often associated with inco ordination of this kind and if such school difficulties arise the child is likely to become depressed and to withdraw from the situation

Unless the disability is very marked it may not cause particular comment or put the child under pressure before school entry Also for the majority of these children, progress at school will most probably be satisfactory if they can be given a certain amount of help and understanding and above all credit for their efforts which will have to be greater than aver age So much of the teaching that takes place in the good infant class is just what these children need Therefore with few exceptions the best time to screen children for this disabil ity may be at school entry or soon afterwards Then the teacher can be alerted to the possibil ity of a child s difficulties and encouragement of efforts and a certain amount of special help may be all that is required There will be some children who are so severely affected that they will need to be educated in a special class or even a special school for example a school for physically handicapped children

DISORDERS OF LANGUAGE DE VELOPMENT

Acquiring one s mother tongue may not be thought of as a learnt skill It is true that the brain has in the words of the linguists the propensities to enable it to extract from the linguistic input the relevant data needed to organise language into a consistent system but the same concept could be applied to many other skills (12) There can be no doubt that environment will affect the richness and com plexity of language and the ability to express one s feelings and ideas These statements ap ply to the normal child and if there are specific difficulties in language development the need for teaching language is even more evident

The acquisition of speech and language may be delayed as the result of a variety of dis abilities some of which can be treated It may be possible to compensate for environmental factors for example in preventing some of the deprivation suffered by mentally and physi cally handicapped children A child with se vere cerebral palsy will live in a very restricted world perhaps consisting of one or two rooms at home and the classroom at school There will be few opportunities of exploring the world and experimenting in order to build up the concepts on which so much of inner lan guage depends It has been shown that the way parents talk to their mentally handicapped child can be over simplified and deprive them of the wider experience of language on which

these causes severe brain damage producing gross mental handicap or obvious forms of cerebral palsy and the lesser degrees of dam age leading to the more subtle disabilities of specific learning disorders The fact that boys are more often affected than girls may be ex plained by the message of the Y chromosome in delaying development as suggested by Oun sted & Taylor (13) If the vulnerability of the brain to damage is directly related to its imma turity and cerebral maturation is slower in boys than girls they will be more at risk They will also have a longer exposure to genetic information good and bad

Possible reasons for failure of integration

Improvement of learning disorders un doubtedly occurs as the child grows older but some degree of disability can remain How ever with increasing age it does become easier to avoid or circumvent the difficulties This stresses the importance of not only trying to help the child with remedial teaching but also *finding* out the child s assets and concentrat ing on these as well so that success is assured in some fields

Also it may mean that the number of con nections made between neurones in the brain is more important than the actual number of cells up to a point anyhow Association seems to underlie so much of learning which is com forting as one grows older as it should mean that you can go on learning to an advanced age even if the neurones are becoming pro- gressively fewer

If this is part of the explanation why do these connections fail? Maybe they are not formed they can be destroyed and sometimes they are not used Dobbing (6) has *shown the* importance of adequate nutrition during the major spurt of brain growth whenever this oc curs In humans it begins soon after mid pregnancy so that if the placental circulation is inadequate during the last trimester the de veloping foetus will be deprived of adequate nutrition and the dendritic connections which grow at such an enormous rate at this time will be stunted Anoxia during pregnancy may be a more frequent cause of brain damage than anoxia at birth and Towbin s (17) work strongly supports this But whenever it occurs connections within the brain may be irrepara bly damaged

There is some evidence in the case of vision anyhow that function exerts an effect on den dritic connections and in maintaining them Interference with input from one eye which prevents integration at a cortical level can have a profound effect on synaptic morpho- logy (8) If this is so to what extent can learn ing affect cortical structure?

There is another factor which may contri bute to difficulties of learning at least among the older children and that is inhibition If a stimulus does not have any particular meaning or interferes with perception in some way or other it will be inhibited A classical example is the amblyopic eye of the squinting child If the same happens in the auditory field why should there not be lazy ears? If auditory stimuli are inhibited in this way it will obvi ously interfere with language development and it may be as important to keep alive an awareness of sound in a child with a severe disorder of this kind as it is to fit a hearing aid to a peripherally deaf child

THE ROLE OF THE DOCTOR

What is the role of the Doctor in all this particularly the hospital-based doctor? He is not an educator and should not presume to advise on teaching techniques but he has a *role to play* and a very important one Many aspects of this are obvious The importance of diagnosing causes and seeking to prevent them has already been stressed Among children with handicaps the disabilities are usually multiple but even now high tone deaf ness is sometimes missed among children with delayed language development and a severe refractive *error* among children with visual perceptual problems Also there are dangers in

speech therapist working together in the classroom there will be a few children who may need the kind of expert help that can only be provided in the special school The method used as Moor House School by Mr Lea (9) is a good example of this with the use of colours to identify nouns verbs and adjectives This seems better than using a predominantly audi tory approach when that is the sensory chan nel most severely affected

READING RETARDATION

Difficulties in learning to read are relatively common although the cause varies widely It seems pointless to become emotional about terminology when it now seems to be generally recognised that there is a group of children who for one reason or another have difficulty in learning to read and spell and are in great need of help

Rutter (15) has defined reading backward ness as an attainment in reading accuracy and comprehension 28 months or more below chronological age and reading retardation a specific disability, as reading accuracy and comprehension 28 months or more below the predicted level on the basis of the child s age and I Q on a modified W I S C

The former can be due to such causes as lack of schooling inappropriate teaching emotional disturbances defective vision and low I Q Children having specific difficulties in learning to read (dyslexia) can be divided into several main groups (1), and it is obviously important to analyse the child s disability be fore deciding on how best to help The largest number of children have a disorder of language function (dysphonetic) They have difficulties with spoken speech which after a while they usually overcome only to find it abnormally difficult to read There is a defect in symbol sound integration They recognise words globally and cannot sort out and blend compo nents Spelling is by sight not by ear

A much smaller group have severe perceptual difficulties (dyseidetic) and can truly be called word blind They cannot perceive letters and words as configurations They are poor spellers but their mistakes are not bizarre Some of them will be clumsy children Children who have both types of dis order will be in great trouble

There are some children who do not fit neatly into any of these groups Some seem to have a very specific defect of visual recogni tion They have no difficulties with spoken language development and are not clumsy They just cannot recognise certain visual symbols correctly They can spell a word ver bally without difficulty but not when they write it down Others have very specific de fects of sequencing and synthesis

This is the kind of information which is needed for planning remedial teaching and it seems logical to base this on the use of unaf fected channels of sensory input whole word techniques for the audio phonic group a phonetic approach for the visuo spatial group

ETIOLOGY OF LEARNING DISORDERS

If these learning difficulties are so frequent it is particularly important to study causes and at tempt to prevent these disabilities Hereditary factors obviously play a part but may have been over emphasised in the past even in the case of dyslexia Barton Childs (5) could pro duce relatively little evidence in favour of ge netic factors determining these learning dis orders It therefore seems likely that the ma jority are acquired disabilities and therefore possibly preventable Studies including one in Manchester (unpublished) on clumsy children favour the kind of pre peri and postnatal disorders which result in brain damage partic ularly hypoxia before and during birth This concept is supported by Drillien s (7) studies in which she found that a third of children born with a birthweight of 2 000 g or less were hand icapped and that in a quarter of these there was evidence of intrauterine hypoxia It seems that a spectrum of disabilities results from

these causes severe brain damage producing gross mental handicap or obvious forms of cerebral palsy and the lesser degrees of damage leading to the more subtle disabilities of specific learning disorders The fact that boys are more often affected than girls may be explained by the message of the Y chromosome in delaying development as suggested by Ounsted & Taylor (13) If the vulnerability of the brain to damage is directly related to its immaturity and cerebral maturation is slower in boys than girls they will be more at risk They will also have a longer exposure to genetic information good and bad

Possible reasons for failure of integration

Improvement of learning disorders undoubtedly occurs as the child grows older but some degree of disability can remain However with increasing age it does become easier to avoid or circumvent the difficulties This stresses the importance of not only trying to help the child with remedial teaching but also finding out the child s assets and concentrating on these as well so that success is assured in some fields

Also it may mean that the number of connections made between neurones in the brain is more important than the actual number of cells up to a point anyhow Association seems to underlie so much of learning which is comforting as one grows older as it should mean that you can go on learning to an advanced age even if the neurones are becoming progressively fewer

If this is part of the explanation why do these connections fail? Maybe they are not formed they can be destroyed and sometimes they are not used Dobbing (6) has shown the importance of adequate nutrition during the major spurt of brain growth whenever this occurs In humans it begins soon after mid pregnancy so that if the placental circulation is inadequate during the last trimester the developing foetus will be deprived of adequate nutrition and the dendritic connections which grow at such an enormous rate at this time will be stunted Anoxia during pregnancy may be a more frequent cause of brain damage than anoxia at birth and Towbin s (17) work strongly supports this But whenever it occurs connections within the brain may be irreparably damaged

There is some evidence in the case of vision anyhow that function exerts an effect on dendritic connections and in maintaining them Interference with input from one eye which prevents integration at a cortical level can have a profound effect on synaptic morphology (8) If this is so to what extent can learning affect cortical structure?

There is another factor which may contribute to difficulties of learning at least among the older children and that is inhibition If a stimulus does not have any particular meaning or interferes with perception in some way or other it will be inhibited A classical example is the amblyopic eye of the squinting child If the same happens in the auditory field why should there not be lazy ears? If auditory stimuli are inhibited in this way it will obviously interfere with language development and it may be as important to keep alive an awareness of sound in a child with a severe disorder of this kind as it is to fit a hearing aid to a peripherally deaf child

THE ROLE OF THE DOCTOR

What is the role of the Doctor in all this particularly the hospital based doctor? He is not an educator and should not presume to advise on teaching techniques but he has a role to play and a very important one Many aspects of this are obvious The importance of diagnosing causes and seeking to prevent them has already been stressed Among children with handicaps the disabilities are usually multiple but even now high tone deafness is sometimes missed among children with delayed language development and a severe refractive error among children with visual perceptual problems Also there are dangers in

allocating a child to a school catering for a particular disability and forgetting that he may have several significant handicaps For example, it is not uncommon for deaf children to have perceptual motor disorders which in their own right would seriously interfere with progress at school The doctor has an important role to play in analysing the child s difficulties Labels may serve their purpose but what one really wants to know is the exact nature of the disability so that a remedial programme can be planned As Kinsbourne (11) has said, if you ask a child to do something and he does not, you can ask again, and on the third occasion you can shout at the child, or work out the components of the request, ask about them separately, and find out which one is not understood This analysis will be much more effective if the doctor is a member of a team with help from the psychologist, speech therapist and physiotherapist

These learning difficulties are no particular respecter of the intelligence level, and especially if there is a degree of mental retardation a realistic view of the child s potential must be made It may help the parents to accept this and the need for special school if the situation is fully discussed and it is pointed out that one of the greatest disservices you can do to a child is to put him in a school situation which *is not meaningful to him*

There are a number of adverse situations at home and at school which the doctor may be able to modify especially with the help of a social worker The children are often under excessive pressures for instance they may spend most of their waking hours doing lessons, or they may be falsely accused of not trying when they are really trying much harder than the average

Emotional problems are an especial concern of the doctor This often involves the whole family and the problems can easily get out of proportion particularly in families with learning high on their list of priorities The doctor can often discuss these problems as someone outside the immediate situation He can point out that there is rarely an ideal solution, and that sometimes the school is doing all it can to help, although of course this is not always so Again apart from helping the child with the learning difficulties he can try and make sure that the child succeeds in some way

The doctor must be in the forefront of those pressing for more efficient services After the diagnosis and assessment he can act as a *questioner, checking on the child s progress* and on the kind and effectiveness of any special help that is given Above all he is in an ideal position to act as a co ordinator of all the various experts that may be needed and he must interpret and explain the various opinions to the parents

Learning difficulties affect many children They are not necessarily referred because of these but may come to the clinics with complaints such as headaches abdominal pain tics and nocturnal enuresis If the disabilities are not recognised for what they are early in school life emotional complications are almost inevitable and these in their turn will delay progress Much of this is preventable and although children can often overcome their difficulties at what cost emotionally and intellectually The failure of potential is difficult to measure but is likely to be large Doctors must play a greater part in helping *these children and if possible as members* of assessment teams whether these are based in hospitals or in the community

CASE REPORT

A CASE OF FOCAL DERMAL HYPOPLASIA (GOLTZ SYNDROME) WITH SOMF NEW ASPECTS

N BEGANOVIĆ and E J P LOMMEN

From the Paediatric Department St Joseph Ziekenhuis Eindhoven the Netherlands

ABSTRACT Beganovic N and Lommen E J P (Paediatric Department St Joseph ziekenhuis Eindhoven the Netherlands) A case of focal dermal hypoplasia (Goltz syn drome) with some new aspects Acta Paediatr Scand 66 255 1977.—A case of Focal Dermal Hypoplasia (Goltz syndrome) diagnosed at birth is reported Some findings not formerly described (hemimelia schizis of the palatum molle and the absence of one um bilical artery) are reported Normal findings in chromosome studies with banding techniques are discussed

KEY WORDS Focal dermal hypoplasia Goltz syndrome X linked dominant inheritance single umbilical artery hemimelia

Focal dermal hypoplasia as a nosological en tity was first described by Goltz et al (1) Up till now 50 cases have been reported in the literature All patients show dysplasia of the skin and several other ectodermal structures Mesodermal structures also are frequently affected Because of the dysplastic character of the syndrome Ishibashi & Kurihara (4) pre fer to name it dysplasia rather than hypoplasia

In the following we shall describe a case diagnosed at birth and associated with some defects not formerly described by other au thors Chromosome investigations by means of banding techniques were carried out

CASE REPORT

The patient a girl was born in October 1975 as the first child of healthy young parents Pregnancy was unevent f l There were no hereditary disorders or congenital malformations in the family The child's weight was only 1960 g (small for date) The placenta was small (375 g) and had only one umbilical artery

Several malformations were noticed (Fig 1) The oc ciput was flat with a short neck There were low set and malformed ears The external auricular canal was normal as were the eardrums There were severe colobomas of the iris the chorioidea and the retina of both eyes and a bilateral microphthalmia There was a short mandibula a broad nasal bridge and flattening of the left side of the face the mouth appeared to be small The gingivae were hypertrofic and showed several elevations with a bony consistence

The uvula was absent and the palatum molle was split The palatum durum was intact as were the maxilla and the lips

The skin showed small spots in a linear arrangement in which the dermis was lacking resulting in herniation of subcutaneous fat through the defects

The neck the right shoulder the abdomen and the buttocks showed larger areas with a complete lack of dermis and epidermis presenting as red decubitus like lesions (Fig 2)

A skin biopsy of the affected areas showed micro scopically a thin and locally absent cutis with fatty tissue reaching up to the epidermis without overlying elastic fibers There was a large umbilical herniation (diameter 4 cm)

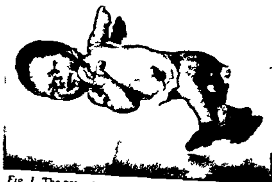

Fig 1 The patient s appearance at 1 day of age

CASE REPORT

SINUS HISTIOCYTOSIS WITH MASSIVE LYMPHADENOPATHY

K BROSTRØM and U BAANDRUP

From the University Department of Paediatrics and the University Institute of Pathology
Kommunehospitalet Aarhus Denmark

ABSTRACT Brostrøm K and Baandrup U (University Department of Paediatrics and University Institute of Pathology Kommunehospitalet Aarhus Denmark) Sinus histiocytosis with massive lymphadenopathy Acta Paediatr Scand 66 257 1977 —The present case report brings to attention an unusual form of massive benign lymphadenopathy which can simulate malignant lymphoma The disease occurs mainly in children and is characterized by a protracted course with painless enlargement of the cervical lymph nodes fever leucocytosis mild anaemia raised erythrocyte sedimentation rate and hypergammaglobulinaemia The diagnosis is confirmed by a quite distinct microscopic picture of the involved lymph nodes SHML is considered to be an unusual response to an infection in an individual with abnormal host defence though this is not confirmed by the investigations undertaken in the presented case

KEY WORDS Sinus histiocytosis benign lymphadenopathy

An unusual form of histiocytosis was first described by Azoury & Reed in 1966 (1) Recently Rosai & Dorfman have analysed 34 cases and have established the disorder sinus histiocytosis with massive lymphadenopathy (SHML) as a clinical and pathologic benign entity (4 5) Most cases of SHML occur in children and are characterized by painless cervical lymphadenopathy often bilateral and of massive proportions Other lymph node groups are sometimes involved A few patients had involvement of soft tissue of the orbit and skin and of lymphoid tissue in the nasopharynx The children are usually in a good general condition Concomitant features are mild fever leucocytosis with neutrophilia anaemia markedly elevated ESR and hypergammaglobulinaemia

The pathologic picture of a lymph node biopsy is quite distinct with capsular and pericapsular fibrosis The normal lymph node architecture is totally disintegrated the sinuses being distended and packed with histiocytes showing pronounced lymphophagocytosis

The lymphadenopathy regresses slowly over years with complete recovery in most cases The aetiology and pathogenesis are not known It is suggested that SHML is the expression of an infection in an immunologically deficient individual (2 3 5)

CASE REPORT

A previously healthy girl developed at the age of 3½ years painless enlargement of the cervical lymph nodes There was no history of a preceding sore throat or febrile episode

At admission her general condition was good During the first few days she ran a low grade fever of maximum 38 5 C On the left side of the neck there was considerable enlargement of lymph nodes (Fig 1) The remaining superficial lymph node groups were unremarkable but roentgenological examination showed moderate enlarged

Fig 2 Cutaneous lesion at the right arm

The left forearm and hand were completely absent and the left upperarm showed a distal fingerlike appendix only consisting of soft tissue The right hand showed a low set thumb and only three fingers and resembled a lobsterclaw There was slight syndactyly of the 4th and 5th toe of the left foot and of the 2nd and 3rd toe of the right foot X ray examinatin showed hypoplasia of the right clavicle There were no rudimentary rests of the bones of the left forearm and hand and the left humerus showed a forkshaped distal ending From the right hand one finger was completely missing Skull vertebrae and other bones seemed to be normal

Intravenous pyelography showed torsion of both kidneys with rather large but otherwise normal pyela

There was no significant elevation of a virus antibody titer and immunoglobulins were found to be normal for age Chromosome studies were performed A normal female karyogram was found in the standard techniques (50 cells counted 7 cells analysed) and also in the banding techniques in an analysis of 6 cells in G banding and Q banding no aberrations were found Especially both X chromosomes appeared to be normal

DISCUSSION

The symptomatology of this child correlates completely with the syndrome of focal dermal hypoplasia as described in older children first by Goltz et al (1) and subsequently by Gorlin et al (3) Ishibashi & Kurihara (4) and Valerius (5) The last author gives a very comprehensive review of the findings at birth in his patient and there is a striking similarity between his description of the epithelial defects in his patient and our findings whereas all other patients described at a later age show a partial repair of these defects

Three findings in our patient have not formely been described

1 The hemimelia found in our patient is unique, other patients show only digital absences or partial aplasia of the forearm (4)

2 No case history mentions the number of umbilical vessels and as Valerius (5) also reports the birth of an affected girl who was small for date the findings of one umbilical artery in our case could be of significance as well in relation to the complexity of symptoms as to the cause of the small for date birth weight

3 Valerius (5) describes a patient with a cheilo gnato-palatoschizis Our patient shows only a schizis of the palatum molle and absence of the uvula

Whereas the focal dermal hypoplasia is supposed to be inherited in an X linked dominant way with a lethal course in male patients (2) several authors have searched in vain for aberrations in the X chromosome (2 4 5 present report) using the standard techniques In addition in our study no abnormality could be detected in the chromosomal substructures as revealed by means of the recently developed banding techniques

CASE REPORT

SINUS HISTIOCYTOSIS WITH MASSIVE LYMPHADENOPATHY

K BROSTRØM and U BAANDRUP

From the University Department of Paediatrics and the University Institute of Pathology Kommunehospitalet Aarhus Denmark

ABSTRACT Brostrøm K and Baandrup U (University Department of Paediatrics and University Institute of Pathology Kommunehospitalet Aarhus Denmark) Sinus histiocytosis with massive lymphadenopathy Acta Paediatr Scand 66 257 1977.—The present case report brings to attention an unusual form of massive benign lymphadenopathy which can simulate malignant lymphoma The disease occurs mainly in children and is characterized by a protracted course with painless enlargement of the cervical lymph nodes fever leucocytosis mild anaemia raised erythrocyte sedimentation rate and hypergammaglobulinaemia The diagnosis is confirmed by a quite distinct microscopic picture of the involved lymph nodes SHML is considered to be an unusual response to an infection in an individual with abnormal host defence though this is not confirmed by the investigations undertaken in the presented case

KEY WORDS Sinus histiocytosis benign lymphadenopathy

An unusual form of histiocytosis was first described by Azoury & Reed in 1966 (1) Recently Rosai & Dorfman have analysed 34 cases and have established the disorder sinus histiocytosis with massive lymphadenopathy (SHML) as a clinical and pathologic benign entity (4 5) Most cases of SHML occur in children and are characterized by painless cervical lymphadenopathy often bilateral and of massive proportions Other lymph node groups are sometimes involved A few patients had involvement of soft tissue of the orbit and skin and of lymphoid tissue in the nasopharynx The children are usually in a good general condition Concomitant features are mild fever leucocytosis with neutrophilia anaemia markedly elevated ESR and hypergammaglobulinaemia

The pathologic picture of a lymph node biopsy is quite distinct with capsular and pericapsular fibrosis The normal lymph node architecture is totally disintegrated the sinuses being distended and packed with histiocytes showing pronounced lymphophagocytosis

The lymphadenopathy regresses slowly over years with complete recovery in most cases The aetiology and pathogenesis are not known It is suggested that SHML is the expression of an infection in an immunologically deficient individual (2 3 5)

CASE REPORT

A previously healthy girl developed at the age of 3½ years painless enlargement of the cervical lymph nodes There was no history of a preceding sore throat or febrile episode

At admission her general condition was good During the first few days she ran a low grade fever of maximum 38 5 C On the left side of the neck there was considerable enlargement of lymph nodes (Fig 1) The remaining superficial lymph node groups were unremarkable but roentgenological examination showed [illegible]

Fig 2 Cutaneous lesion at the right arm

The left forearm and hand were completely absent and the left upperarm showed a distal fingerlike appendix only consisting of soft tissue The right hand showed a low set thumb and only three fingers and resembled a lobsterclaw There was slight syndactyly of the 4th and 5th toe of the left foot and of the 2nd and 3rd toe of the right foot X ray examinatin showed hypoplasia of the right clavicle There were no rudimentary rests of the bones of the left forearm and hand and the left humerus showed a forkshaped distal ending From the right hand one finger was completely missing Skull vertebrae and other bones seemed to be normal

Intravenous pyelography showed torsion of both kidneys with rather large but otherwise normal pyela

There was no significant elevation of a virus antibody titer and immunoglobulins were found to be normal for age Chromosome studies were performed A normal female karyogram was found in the standard techniques (50 cells counted 7 cells analysed) and also in the banding techniques in an analysis of 6 cells in G banding and Q banding no aberrations were found Especially both X chromosomes appeared to be normal

DISCUSSION

The symptomatology of this child correlates completely with the syndrome of focal dermal hypoplasia as described in older children first by Goltz et al (1) and subsequently by Gorlin et al (3) Ishibashi & Kurihara (4) and Valerius (5) The last author gives a very comprehensive review of the findings at birth in his patient and there is a striking similarity between his description of the epithelial defects in his patient and our findings whereas all other patients described at a later age show a partial repair of these defects

Three findings in our patient have not formely been described

1 The hemimelia found in our patient is unique other patients show only digital absences or partial aplasia of the forearm (4)

CASE REPORT

INSULIN AND GROWTH HORMONE SECRETION IN A LEUKAEMIC GIRL WITH HYPOTHALAMIC SYNDROME

G SCHILIRÒ A RUSSO A SCIOTTO and R VIGO

From Paediatric Clinics I and II University of Catania Catania Italy

ABSTRACT Schiliro G Russo A Sciotto A and Vigo R (Paediatric Clinics I and II University of Catania Catania Italy) Insulin and growth hormone secretion in a leukaemic girl with hypothalamic syndrome Acta Paediatr Scand 66 261 1977.—The authors report a girl with acute lymphoblastic leukaemia presenting hypothalamic syndrome characterized by meningeal leukaemia hyperphagia and obesity Insulin and growth hormone secretion studied with arginine and insulin stimulation tests showed a high peak of serum insulin and no response of growth hormone Insulin and growth hormone responses to these tests reverted to normal after intrathecal methotrexate

KEY WORDS Insulin growth hormone leukaemia hypothalamic obesity

The central nervous system (CNS) involvement during acute leukaemia is one of the most important problems in the treatment of this disease Hypothalamic hyperphagia is a rare form of CNS involvement first described by Sansone (18) in 1954 Since then many other cases have been reported (1 2 3 4 5 10 11 13 ?0 21) but all the reports are limited to the description of the clinical picture and the pathological findings without endocrine studies Only in one case (3) a decreased level of thyrotrophic hormone and absence of gonadotrophic activity has been reported

We have studied the insulin and growth hormone (HGH) secretion in a leukaemic girl with hypothalamic hyperphagia and obesity before and after the successful intrathecal treatment with methotrexate (MTX)

CASE REPORT

A 10-year-old girl was admitted into our clinic in October 197 because of pain in the leg pallor and low grade fever Bone marrow aspiration revealed a typical picture of acute lymphoblastic leukaemia Chest X ray revealed no mediastinal involvement Treatment was started with triamcinolone (100 mg/m²/day orally) and vincristine (1 5 mg/m²week i v) and complete remission was achieved after four weeks The patient was discharged with maintenance therapy of 6-mercaptopurine (50 mg/m²/day) and MTX (10 mg/m²/twice a week) In March 1973 the patient presented CNS symptoms but bone marrow remained in complete remission Treated with orthovoltage cranial irradiation (1?00 rads) and low doses of intrathecal MTX (10 μg/kg) at first daily and thereafter every –3 days (14) the patient achieved complete remission after 3 weeks Further administration of intrathecal MTX was very irregular because the parents often broke the appointments In July 1974 at the age of 11 years and 8 months the patient was readmitted because she had had hyperphagia and excessive weight gain for three weeks Physical examination showed cushingoid face obesity and minimal meningeal signs Height was 140 cm (mean for her age 138 cm) weight was 56 kg (mean for her age 31 kg) The bone marrow was in complete remission Skull X ray EEG and fundoscopy were normal Skeletal age was also normal Lumbar puncture showed an increased pressure of the spinal fluid and the presence of 12 0 blast cells/ml The patient was treated with intrathecal MTX (5 mg/m /week) and her appetite rapidly decreased The spinal fluid was clear after the second injection of MTX and the girl lost 10 kg within one month

person with immunological deficiency (2 3, 5) This may be the fact but we are unable to confirm it by the investigations done in the presented case

Our patient was treated with antibiotics but without success as is the experience from other cases Some patients have been submitted to cytostatics corticosteroids and/or radiotherapy without benefit at best they have not been harmed (5) Given the now established benign nature of SHML it can be concluded that no specific therapy is warranted and that a re assuring approach about the self limited nature of the condition be given to the parents

the possibility that the low secretion of HGH is due to the infiltration of leukaemic cells in the hypothalamic pituitary region It has been demonstrated that levels of HGH are low and do not respond to the stimulation tests in children with histiocytosis X and diabetes in sipidus (12) This observation suggests that the leukaemic infiltration into the hypothalamic pituitary region may impair the HGH secretion as in obesity No information is however available about HGH levels after treatment in histiocytosis X In our patient the intrathecal treatment with MTX rapidly produced a de crease of the appetite and marked weight loss showing that the hyperphagia may be due to leukaemic infiltration of the hypothalamus

Figs 1–3 Arginine and insulin tolerance tests before treatment of the hypothalamic syndrome

METHODS

Arginine tolerance test L Arginine hydrochloride in saline solution (0 5 g/kg) was administered intravenously during 30 min

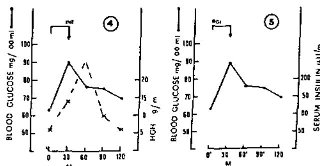
Insulin tolerance test Regular crystalline insulin was *injected intravenously at the dosage of 0 1 units/kg*

In both tests blood samples were obtained at 0 30 60 90 120 min The serum was separated at 4 C and stored at −20 C until assayed The blood glucose was measured by a specific glucose oxidase method serum insulin and HGH were determined in triplicate by standard radioimmunoassay techniques (9 19) The tests were performed before treatment with intrathecal MTX and three months after the recovery

Nine normal children (3 males and 6 females) of age ranging from 10 to 12 years were tested as controls

RESULTS

The graphs 1–5 report the results of these studies The arginine tolerance test before treatment produced an increase of the blood glucose during the infusion which then gradually dropped to the normal values The serum insulin showed a very high peak whereas the HGH was *completely unresponsive* (Figs 1 and 2) The insulin tolerance test showed also a normal response of blood glucose and no response of HGH (Fig 3) Control subjects showed responses between the normal range in both tests (Figs 1–3)



After treatment and recovery the arginine tolerance test showed a return to the normal responses of serum insulin and HGH (Figs 4 and 5)

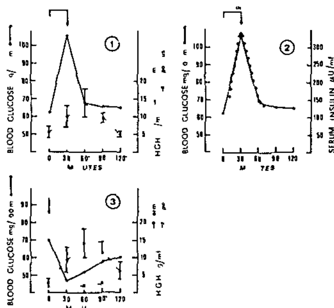
DISCUSSION

The main sign of the observed syndrome is hyperphagia which distinguishes it from the common leukaemic meningoencephalitis and *obesity is caused by this excessive appetite* The hypothalamic infiltration by leukaemic cells has been demonstrated in some of the reported cases of the syndrome (4 5 18 21) Because of the normal appearance of the hypothalamic nuclei in some cases it has been suggested that even the increased spinal fluid *pressure with dilatation of the third ventricle* may mechanically produce a hypothalamic injury (17)

A low level of HGH with decreased response to the stimulation tests has been found both in experimental obesity (8 15) and in the obesity of adults and children (6 7 16) The *study of HGH in our patient demonstrates that* the response in hypothalamic obesity is similar to that reported in other types of obesity The identical behaviour of HGH in obesity of different aetiology the rapid normalization of the basal HGH level and the normal response to the stimulation tests after treatment and *weight reduction support the opinion that* the decreased secretion of HGH is a secondary effect of obesity

However in our case we can not rule out

Figs 4 and 5 Arginine tolerance test after treatment and recovery



the possibility that the low secretion of HGH is due to the infiltration of leukaemic cells in the hypothalamic pituitary region It has been demonstrated that levels of HGH are low and do not respond to the stimulation tests in children with histiocytosis X and diabetes insipidus (12) This observation suggests that the leukaemic infiltration into the hypothalamic pituitary region may impair the HGH secretion as in obesity No information is however available about HGH levels after treatment in histiocytosis X In our patient the intrathecal treatment with MTX rapidly produced a decrease of the appetite and marked weight loss showing that the hyperphagia may be due to leukaemic infiltration of the hypothalamus

Figs 1–3 Arginine and insulin tolerance tests before treatment of the hypothalamic syndrome

METHODS

Arginine tolerance test L Arginine hydrochloride in saline solution (0 5 g/kg) was administered intravenously during 30 min

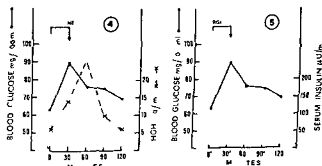
Insulin tolerance test Regular crystalline insulin was injected intravenously at the dosage of 0 1 units/kg

In both tests blood samples were obtained at 0 30 60 90 120 min The serum was separated at 4 C and stored at −20 C until assayed The blood glucose was measured by a specific glucose oxidase method serum insulin and HGH were determined in triplicate by standard radioimmunoassay techniques (9 19) The tests were performed before treatment with intrathecal MTX and three months after the recovery

Nine normal children (3 males and 6 females) of age ranging from 10 to 12 years were tested as controls

RESULTS

The graphs 1–5 report the results of these studies The arginine tolerance test before treatment produced an increase of the blood glucose during the infusion which then gradually dropped to the normal values The serum insulin showed a very high peak whereas the HGH was completely unresponsive (Figs 1 and 2) The insulin tolerance test showed also a normal response of blood glucose and no response of HGH (Fig 3) Control subjects showed responses between the normal range in both tests (Figs 1–3)



After treatment and recovery the arginine tolerance test showed a return to the normal responses of serum insulin and HGH (Figs 4 and 5)

DISCUSSION

The main sign of the observed syndrome is hyperphagia which distinguishes it from the common leukaemic meningoencephalitis and obesity is caused by this excessive appetite The hypothalamic infiltration by leukaemic cells has been demonstrated in some of the reported cases of the syndrome (4 5 18 21) Because of the normal appearance of the hypothalamic nuclei in some cases it has been suggested that even the increased spinal fluid pressure with dilatation of the third ventricle may mechanically produce a hypothalamic injury (17)

A low level of HGH with decreased response to the stimulation tests has been found both in experimental obesity (8 15) and in the obesity of adults and children (6 7 16) The study of HGH in our patient demonstrates that the response in hypothalamic obesity is similar to that reported in other types of obesity The identical behaviour of HGH in obesity of different aetiology the rapid normalization of the basal HGH level and the normal response to the stimulation tests after treatment and weight reduction support the opinion that the decreased secretion of HGH is a secondary effect of obesity

However in our case we can not rule out

Figs 4 and 5 Arginine tolerance test after treatment and recovery

the possibility that the low secretion of HGH is due to the infiltration of leukaemic cells in the hypothalamic pituitary region It has been demonstrated that levels of HGH are low and do not respond to the stimulation tests in children with histiocytosis X and diabetes insipidus (12) This observation suggests that the leukaemic infiltration into the hypothalamic pituitary region may impair the HGH secretion as in obesity No information is however available about HGH levels after treatment in histiocytosis X In our patient the intrathecal treatment with MTX rapidly produced a decrease of the appetite and marked weight loss showing that the hyperphagia may be due to leukaemic infiltration of the hypothalamus

LETTER TO THE EDITOR

On Palpation of the Femoral Pulse in the Newborn

Sir

Most textbooks in pediatrics (1 2 4) and in pediatric cardiology (3) rightly stresses the importance of including palpation of periferal pulses as part of the physical examination of any child

However most medical students and junior doctors and in fact not so few pediatricians find it somewhat difficult and timeconsuming to palpate the femoral artery This is especially true for the routine examination of the newborn at the maternity ward where several babies are screened and the doctors time schedule often tight The difficulties encountered are probably due to the palpation technique used a technique which the doctor or student originally learnt during his first basic training in physical examination on adults The use of the tip of indexfinger may be useful in the adult but is difficult in the crying and struggling baby The textbooks cited above offer no description of technique to be used

The grip and procedure illustrated (Fig 1) has proven to be useful The baby s right thigh and knee is grasped gently with the investigator s left hand and the tumb placed in the groin With this grip the thumb is automatically placed parallel to and over the long axis of the femoral artery and the pulse is readily located The grip is similar to the one used in the Barlow manoeuver when testing for congenital hip dislocation and the two tests could therefore be performed in connection with each other

According to tradition it is thought to be wrong and unprofessional to use the thumb when palpating but my own experience and that of others who have been introduced to this technique have convinced me that this is an exeption to that rule

ANNOUNCEMENT

The Czechoslovak Medical Society J E Purkyne and The Czechoslovak Pediatric Society will organize from July 4 to 6 1977 the 19th Pediatric Congress with International Participation The main topics of the Congress are

1 Nourishment of the suckling and the infant
2 Malabsorption syndrome Digestive enzymes
3 Diencephalohypophyseal system Adrenal cortex
4 Diagnostic and therapeutic actualities

Professor Dr Kamil Kubát DrSc is President of the Congress Enquiries for further particulars should be ad dressed to the Czechoslovak Medical Society J E Pur kyně 19th Pediatric Congress 1?0 26 Praha 2 Sokolská 31

Preparation of Manuscripts

Contributors are requested to pay particular attention to the following rules governing the preparation of manuscripts *Failure to follow these rules is a frequent cause of delay in the publication of articles and may result in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate to the office of the Managing Editor Professor C. G Bergstrand, Department of Paediatrics Malmö Allmänna Sjukhus, S-214 01 Malmö Sweden mailed flat and transmitted by first class mail. They should be double-spaced, typewritten on one side of the paper with wide margins. Authors should exercise particular care in the preparation notation and description of figures and tables. Each table must be accompanied by a descriptive title typed above the table to which it refers. A suitable legend must be provided for each figure. Oversized original illustrations should be photographed and a print on glossy paper submitted A separate *title page* is necessary and should bear a) the title b) the initials and names of the authors c) the institution of origin Below the list of *references* the principal author should state his address to which *the proofs* are to be sent.

A short *abstract* not exceeding 200 words must accompany each manuscript informing about problem, methods, results and conclusions Unexplained abbreviations and *references* are not allowed The abstract must be typed on a separate sheet and styled as illustrated

ABSTRACT Köhler L. and Holst, K. (Department of Paediatrics, *University Hospital*, Lund Sweden) Dental health *of four* year-old children Acta Pædiatr Scand 00

An unselected population of 1 567 four year-old children

KEY WORDS Pre-school children, caries, gingivitis

A *summary* is usually *not* necessary but may be allowed if the author (*or the Editor*) finds it essential A summary should be typed immediately after discussion"

References to the literature should be limited to those quoted by the author The reference list should be arranged alphabetically and numbered, giving name of author (authors) initials full title of paper name of journal abbreviated in accordance with the style of *Index Medicus* (*New Series*) followed by the volume number page number and year *In this system of abbreviation periods are omitted*

1 Brecher G & Stohlman, F., Jr Humoral factors in erythropoietin. *In* L. M Tocantins & R. Penn (eds.) *Progress in hematology* Grune & Stratton, New York 1959 p 110.
2 Smith, C. A. *The physiology of the newborn infant* Thomas, Springfield Ill. 1967 3rd ed., vol. 2, p 120
3 Vedra B & Ulrych, J., Anaerobiosis in normal and asphyxiated premature newborns 2. Four approaches. *Acta Paediatr Scand 49 129 1960.*

Italics are marked in the manuscript by underlining.

Abbreviations must conform to accepted standards. When in doubt authors are advised to consult a recent issue of the journal. The SI system should be used. Laboratory slang, clinical jargon and colloquialisms must be avoided.

Proofs and Reprints Galley proofs will be sent to the principal author by the printer The master *proof should be returned to the Managing Editor together with the manuscript within three days and by air mail if received by air mail.* Reprints of articles published must be ordered, by separate application, from *Almqvist & Wiksell S 751 81 Uppsala, Sweden,* to whom cheques money orders and drafts should be *made payable*

Manuscripts books for review and correspondence relating to the editorial management should be sent to the Managing Editor Department of Paediatrics, Malmö Allmänna Sjukhus S-214 01 Malmö Sweden. Published manuscripts are not returned unless *requested*

BOOK REVIEWS

Peter M Jeavons & Graham F A Harding Photo*sensitive epilepsy* 121 pp illus *Clinics in Developmen*tal Medicine No 56 Spastics International Medical Publications W Heinemann Medical Books Ltd London 1975 £4 50

The authors a clinician (P J) and a scientist (G H) have written an excellent book on the sensitivity to natural or artificial flickering light which is an interesting epileptic phenomenon In the first part of the book there is a review of the literature about clinical aspects of photosensitivity laboratory studies with photostimulators and EEG responses to photic stimulation and therapy in photosensitive epilepsy The second part deals with clinical and laboratory studies of 454 photosensitive patients referred to the EEG Departments of Dudley Road Hospital and the Children s Hospital in Birmingham (U K) between 1961 and 1973 The series included 332 patients with fits provoked by the flickering light of daily life and 122 cases with fits not triggered by light but whose EEGs showed abnormalities during photic stimulation in the laboratory The onset of their photosensitive epilepsy was before 17 years of age in 79% of the cases with a maximum around puberty Of all patients 63% were females Watching T V induced fits in 299 cases 30 of them were impulsively attracted to the T V screen Systematic and interesting investigations of clinical and EEG responses to light flashes with various physical properties were performed in order to develop a standardised technique for photic stimulation and elucidate the mechanism behind photosensitivity The chapter on therapy deals with the avoidance of stimulus conditions which may provoke fits the use of sodium valproate as anticonvulsant and the design of protective spectacles

This is a most valuable book to electroencephalographers and epileptologists With its clarity and balance its many case histories 60 illustrations of good quality and a well chosen and useful bibliography it is however of real interest and value to all who are concerned with clinical aspects of brain function

Karl Magnus Herrlin

H C Shirkey (ed) *Pediatric therapy* 5th ed 1405 pp illus The C V Mosby Company St Louis 1975 US $41 50

Pediatric therapy is now out in its 5th edition the 4th one was published only 3 years ago and right from the beginning one can say that there are no remarkable new changes in this edition The size of the book is about the same 1405 pages written by altogether 117 contributors There are 490 modern and good illustrations

Since the 1st edition back in 1964 Pediatric therapy has followed roughly the same course and covers roughly the same fields of pediatric therapy Compared with the latest edition in 1972 there are exactly the same chapters in this new edition although some of the chapters have been brushed up in order to keep pace with modern development in pediatric therapy

By tradition Pediatric therapy has had strong chapters concerning drug treatment adverse drug reactions general therapy and infectious diseases—these chapters are still strong and up to date Other chapters may be called weak ones and those are still weak for instance the chapter concerning the newborn infant pediatric psychiatry allergic disorders and pediatric neurology The presentation in these chapters shows that it today no longer is appropriate to deal with all fields of pediatrics in one volume It is almost impossible for instance to cover modern aspects of treatment in pediatric neurology in 18 pages and the newborn infant in 20 pages!

Editors also of classical textbooks such as Pediatric therapy have to accept that modern development is so rapid and complicated that the time has passed when one could cover all aspects in one textbook However with this general critical remark in mind Pediatric therapy is still an extremely useful and valuable textbook especially concerning drug therapy in pediatrics!

Ove Petersson

PAEDIATRICS TODAY AND TOMORROW[1]

BO VAHLQUIST[2]

Paediatrics today and tomorrow—this is rather a question of futurology Of this it has been said that the only certainty is that the future arrives more quickly than we have imagined and that it is different from what we have assumed The distance in time up to the year 2000 is no longer than that back to 1952—and for many of us that does not seem such a long time ago

Our society is undergoing a fundamental process of change Man as a biological individual is not affected by this but his development and adaptation to the constantly changing environment are being considerably influenced No prognoses can be made about tomorrow s paediatrics without first considering our expectations concerning future alterations in the life milieu of children and adults and possible further advances in medical research

During the past century the general standard of living in our Scandinavian countries has been raised tremendously *At the same time* the change over from an agricultural to an industrial community has basically altered our *ancient traditions* The extended family with numerous offspring has given way to the nuclear family with limited offspring and poor contact with relatives A large proportion of women have obtained work away from the home As a result the need for daily institutional care of children of preschool age has greatly increased There is reason to fear that tomorrow s parents may tend to consider even the care of healthy children as primarily the concern of the community with a reduction of their own responsibility and greater insecurity on the part of the children as a result The development of mass media especially television is progressively replacing active contact with play sports and nature by standardized passive consumption of filmed material

Advances in medical research such as sulphonamides antibiotics and vaccines have favoured paediatrics probably more than any other of the traditional medical disciplines It seems as if the most beautiful fruits have already been harvested—as long as our hopes of effective measures against the constantly prevalent common cold are not realised

Let us now consider for a moment some facts concerning the *population development* which so especially concerns the paediatrician The birth rate has declined greatly in all Scandinavian countries with immediate effects on the size of the child population In the mid *1940s 135 000* children were born annually in Sweden while in 1975 this figure was down to 103 000 In the Scandinavian countries today *children* under 15 years of age constitute no more than about 1/5 of the total population A stabilisation of this development might possibly be expected in the years to come It seems that both contraception and legal abortions have now reached some degree of balance One advantage of these radical measures is that the majority of the children now entering our part of the world are wanted children

The infant mortality in the Scandinavian

Paediatrics today and *tomorrow—this is rather* a question of futurology Of this it has been said that the only certainty is that the future arrives more quickly than we have imagined and that it is different from what we have assumed The distance in time up to the year 2000 is no longer than that back to 1952—and for many of us that does not seem such a long *time ago*

Our society is undergoing a fundamental process of change Man as a biological individual is not affected by this but his development and adaptation to the constantly changing environment are being considerably influenced No prognoses can be made about tomorrow s paediatrics without first considering our expectations concerning future alterations in the life milieu of children and adults and possible further advances in medical research

During the past century the general standard of living in our Scandinavian countries has been raised tremendously At the same time the change-over from an agricultural to an in*dustrial community* has basically altered our ancient traditions The extended family with numerous offspring has given way to the nuclear family with limited offspring and poor contact with relatives A large proportion of women have obtained work away from the home As a result the need for daily institutional care of children of preschool age has greatly increased There is reason to fear that tomorrow s parents may tend to consider even the care of healthy children as primarily the concern of the community with a reduction of their own responsibility and greater insecurity on the part of the children as a result The development of mass media especially television is progressively replacing active contact with play sports and nature by standardized passive consumption of filmed material

Advances in medical research such as sulphonamides antibiotics and vaccines have favoured paediatrics probably more than any other of the traditional medical disciplines It seems as if the most beautiful fruits have already been harvested—as long as our hopes of effective measures against the constantly prevalent common cold are not realised

Let us now consider for a moment some facts concerning the *population development* which so especially concerns the paediatrician The birth rate has declined greatly in all Scandinavian countries with immediate effects on the size of the child population In the mid 1940s 135 000 children were born annually in Sweden while in 1975 this figure was down to 103 000 In the Scandinavian countries today children under 15 years of age constitute no more than about 1/5 of the total population A stabilisation of this development might possibly be expected in the years to come It seems that both contraception and legal abortions have now reached some degree of bal*ance One advantage* of these radical measures is that the majority of the children now entering our part of the world are wanted children

The infant mortality in the Scandinavian

[1] Inaugural address delivered on June 30 1976 on the occasion of the 18th Nordic Paediatric Congress Århus Denmark

[2] Em Professor of Paediatrics Department of Paediatrics University Hospital Uppsala Sweden

countries lies at an unprecedentedly low level—both Finland and Sweden now report figures below 10/1 000 liveborns This means that whole nations now approach the low level that 50 years ago could only be claimed by the royal families The mortality after the first year of life has shown a similar trend The time is past when small coffins were frequently seen being carried for burial at our church yards When on the other hand a child does die the loss is perhaps even harder to bear

Underlying the previously high mortality in infancy lay two major disease complexes—serious infectious diseases and severe malnutrition The latter has long since been eliminated and the former is well on its way to this goal

While many of the old diseases have been completely eradicated (polio, diphtheria rheumatic fever tuberculosis etc) or greatly reduced (pneumonia whooping cough scarlet fever meningitis sepsis etc) others have gained relative importance Robert J Haggerty speaks of the new morbidity This concept includes both physical and mental problems In the former category we find for example the sudden unexpected death in infancy childhood accidents the battered child syndrome the allergic diseases and the comprehensive care of the handicapped child and in the latter behavioural disturbances and adolescent and social problems Paediatricians active in outpatient and ambulatory care in particular will be concentrating their attention increasingly on the new morbidity in the next decades

In recent years there have been lively debates in all the Scandinavian countries on the *organisation of medical care* with special regard to primary care (lowest acceptable level of care) It is important that this should as far as possible be the responsibility of the general practitioner the specialist being reserved only for selected patients But the paediatric specialist in outpatient care is also a general practitioner—for children! Parents are increasingly expressing a wish to consult a paediatrician when their child is ill The total volume of the child medical care need is extensive—it is estimated that about 1/4 of all outpatient cases are children In addition there is a need for extensive engagement in all sorts of child health activities

The Swedish Board of Health and Welfare have now devised a plan whereby special district paediatricians are to be established It is intended that with the expansion of primary care and as more paediatricians become available such positions shall be created throughout the country It will be several decades however before this plan can be fully realised The present number of paediatricians has to be more than doubled

I have spoken of paediatricians in ambulatory care as general practitioners for children In hospital care, also paediatricians with a good all round training are required But here there is an increasing demand especially in the large university hospitals for paediatricians with wide experience in special fields such as neurology habilitation cardiology allergology etc For a long time such specialisation took place on the basis of personal interest but more recently in many places permanent specialist positions have been established Continued development in this direction is to be expected Space does not allow a detailed discussion here but I should like to touch upon one question namely *perinatal care* The valley of the shadow of birth is a sombre expression As little as 25 years ago 30–40/1 000 children in Sweden died in the perinatal period i e in the final stage of pregnancy during the delivery itself or in the first week of life This mortality rate was as high as during the entire subsequent period up to the age of 30 years It is one of the most beautiful examples of the results of improved medical efforts and especially of cooperation over the borders between obstetricians anaesthesiologists and paediatricians that the perinatal mortality has now fallen to 13/1 000 In one hospital Danderyd near Stockholm where this question has received special at

tention a figure of 8/1 000 has been attained for three consecutive years mainly by simple measures At the same time investigations in Gothenburg as well as in other parts of Scandinavia have shown that among the children whose lives have been saved in this way there has been no increase in the frequency of handicaps There is no doubt that augmented efforts in perinatal care will be one of the characteristics of the paediatrics of tomorrow

In this connection I will make a few brief comments on the need of *hospital beds for children* If we estimate that to an increasing extent children will receive care at paediatric clinics regardless of the nature of their basic disease the old rule of thumb of 30 beds per 100 000 population should not become much lower

More important than the number of beds is the way in which they are utilized and the quality of the general care of the children There have been considerable improvements in recent years—parents are encouraged to be near their child systematic play therapy and school lessons are favoured and painful and frightening procedures are avoided as far as possible But even today not all paediatric clinics live up to reasonable demands in these respects and certain alterations in the medical care milieu resulting from structural changes in society are of a directly negative nature Shortened working hours and increasingly quick turn-over of staff result in a reduction of the children s sense of security

In paediatric care both inpatient and ambulatory *behavioural disturbances* are playing a progressively larger role There is clearly not only a relative but also an absolute increase in this respect Certain features in the development of our society provoke such disturbances at the same time as the uncertainty of the parents lowers their own and their child s tolerance limit Often it is a case of a simple problem where enlightenment on normal biological and age variations will be sufficient "treatment In other cases advice and guidance in the field of minor child psychiatry is needed More and more frequently behavioural disturbances prove to have arisen from social problems Our welfare state seems rather to constitute a breeding ground for such disturbances and it seems likely that this will be increasingly reflected in tomorrow s paediatrics The need for intimate collaboration with various welfare agencies will then become even greater

Adolescence easily becomes a no man s land In several places Finland in particular special adolescent clinics have been organised following the pattern established in the USA The predominant problems are of a psychosomatic hypochondrial and emotional nature on the one hand and endocrinological and gynaecological—including contraception—on the other These clinics have been found to fill an important need and this type of activity will probably be extended in the future More attention than previously should also be paid in this connection to invoking sound dietary habits in young people

Preventive health care It is clear that in childhood in particular preventive health care has brought great benefits In Sweden a government supported activity in this field was launched in 1938 It rapidly gained momentum and today well covers the population Health care begins at birth or rather before birth and continues at child health centres day nurseries and schools The linking key figure is often the district nurse who has the best contact with the family and represents continuity The paediatrician cannot afford the same amount of time for each patient but his or her role in providing support consultation and instruction cannot be overestimated

There is much discussion today about the *special health screening of 4 year olds* In Sweden this began in 1967 and it is now being carried out to varying extents and by varying methods in all Scandinavian countries It may and should be regarded as a link in the general preventive health care of preschool children It is of value not only because of the new sometimes very important observations that

countries lies at an unprecedentedly low level—both Finland and Sweden now report figures below 10/1 000 liveborns This means that whole nations now approach the low level that 50 years ago could only be claimed by the royal families The mortality after the first year of life has shown a similar trend The time is past when small coffins were frequently seen being carried for burial at our church yards When on the other hand a child does die the loss is perhaps even harder to bear

cigarett smoking sexual promiscuity over nutrition wrong dietary habits etc are enormous Against this background the efforts to influence the underlying attitudes seem fumbling and uncertain It is difficult to believe that the life style aberrations can be allowed to continue These problems certainly deserve increasing involvement on the part of the medical profession

Ethical problems Hitherto these have been discussed mostly in relation to clinical research In the future they will certainly become more topical and more penetrating also in practical health care including paediatrics Economic and personnel limitations may force decisions concerning priorities that will prevent patients from benefiting from new advances in medical research Questions on how far the concentration of resources on the incurable should be carried may become a painful reality Genetic counselling may in its implementation involve intricate decisions

In this connection one particular problem of ethics may be mentioned—that of the doctor s liability In the USA we are witnessing today a wave of claims for damages against doctors for malpractice—true or supposed Our experiences of this in Scandinavia hitherto are only the beginning

Paediatricians and the Third World Social responsibility today does not end at national borders We live in a rapidly shrinking world Satellite pictures reach our eyes almost at the same moment as the dramatic events that they depict are taking place in Beirut Johannesburg or Luanda The victims of starvation in Ethiopia Sahel and Bangladesh gaze at us with dark and desperate eyes What do we do for our brothers and sisters in the Third World? The paper mills grind at large conferences but the practical result is usually desperately insufficient to diminish the constant silent need among hundreds of millions of children in the developing countries It is hardly likely that their lot will be improved appreciably until radical political changes have been made Regimes are needed that will become unequivocably involved for the benefit of the enormous groups of indigent people and which will place the needs of mothers and children not last but first

In relation to the world as a whole the Scandinavian countries are small both population wise and economically but their voices are nevertheless relatively powerful It is important that their messages be based on firm ground established also by the collaboration of the medical profession Many Scandinavian colleagues especially paediatricians have taken part and are doing so today in development assistance in the Third World Their number could be greater however—we could afford this

During the 15 years in which I myself have been engaged in related problems the aim and form of development assistance has changed in many respects In 1960 40 of Africa s 49 states were under Colonial rule whereas today only three remain The numerous new independent states often with Marxist ideals are filled with a strong will to shape their own development and their own destiny Cooperation from industrialized countries is still relevant in the field of health care but the roles of the expatriate resource persons have changed and the demands for good previous knowledge of conditions prevailing in the Third World and willingness to accept national priorities in health care have increased

As part of a systematic training for work in Third World countries 10-week training courses for doctors and nurses combined have been run in Sweden since 1973 under the auspices of the National Board of Health and Welfare in cooperation with the Swedish International Development Authority (SIDA) and with collaboration between university institutions in Uppsala and Stockholm Altogether more than 200 doctors and registered nurses most of them already contracted for work in developing countries have now received their diploma To a limited extent the courses which are held twice a year have also been open to participants from the neighbouring

are made concerning impaired vision and hearing etc but also because it has aroused interest in new test methods, promoted group activity and initiated the establishment of new posts The chief officer of child health care at county level has become the central figure linking together the entire chain of preventive health care measures at preschool ages

The district paediatricians in Sweden often use one third (or more) of their working time for preventive care Benefits may be assumed not only in the form of improved health in childhood but also far later in adult years

School health care at least in Sweden has not yet achieved an ideal form This autumn we foresee a new parliamentary committee report in this field probably without major proposals for change Recommendations are expected for renouncing the strict health care nature of this service to allow the addition of simple medical treatment

The school doctor has much to gain by following the paediatric model for contacts with the pupils and their parents But he or she also needs to be able to collaborate—for example with teachers psychologists and social workers In Sweden there has been much debate about SIA—a study on the school routine This aims at a more integrated school day team work and freer availability of resources and in general a more open school The health care of school children will certainly be affected but little of this has been mentioned in the committee reports

The paediatrician as a group worker The development has long moved in the direction of increasing specialisation not only in medicine but in all occupational fields It is unlikely that this trend will reverse and it therefore has to be balanced by group work One has to learn to understand and speak the language of others while at the same time preserving one s own special ability For the paediatrician this means that he must be as well versed as ever in the basic knowledge of the growth and development of the child and its mode of reaction to different environmental factors or in his detailed knowledge of all the major childhood diseases—including the psychosomatic conditions and minor child psychiatry In these areas the paediatrician cannot be replaced And group work is not only a question of willingness to cooperate and freedom from prestige—to be successful it requires solid knowledge on the part of its participants

The paediatrician s working day For the majority of paediatricians—especially those in district care—the work is not particularly exciting or glamorous perhaps not even interesting in the sense that it gives the opportunity to subtle diagnoses or dramatic cures Rather it is a strenuous sometimes monotonous job of a service type where the reward lies in the knowledge that one has close contact with the patient and his family and is at hand in times of trouble with encouragement and good advice With the right selection of candidates to medicine as a profession and especially to paediatrics this should be satisfaction enough

The paediatrician as a custodian over children s interests In American paediatric circles the paediatrician has sometimes been referred to as the ombudsman of children Pleasingly enough in our Scandinavian countries there has always been a strong social interest among paediatricians They have not been satisfied with merely treating a child s illness but have gone one step further In this way they have exerted considerable influence in preventive and social paediatrics There would seem reason to ask however in these times of radical change if the voice of the paediatrician should not be heard even louder in current debates

The life style crisis In the criticism against modern medicine that flares up from time to time and that may be expected to increase in strength in coming years it has been pointed out that the severe health problems of the wealthy nations can only be solved by a change in the general life style The harmful effects on the individual and community of traffic accidents alcohol and misuses of drugs

cigarett smoking sexual promiscuity over nutrition wrong dietary habits etc are enormous Against this background the efforts to influence the underlying attitudes seem fumbling and uncertain It is difficult to believe that the life style aberrations can be allowed to continue These problems certainly deserve increasing involvement on the part of the medical profession

Ethical problems Hitherto these have been discussed mostly in relation to clinical research In the future they will certainly become more topical and more penetrating also in practical health care including paediatrics Economic and personnel limitations may force decisions concerning priorities that will prevent patients from benefiting from new advances in medical research Questions on how far the concentration of resources on the incurable should be carried may become a painful reality Genetic counselling may in its implementation involve intricate decisions

HEREDITARY CHOLESTASIS COMBINED WITH PERIPHERAL PULMONARY STENOSIS AND OTHER ANOMALIES

N T HENRIKSEN F LANGMARK S J SØRLAND O FAUSA
S LANDAAS and Ø AAGENAES

From the Department of Paediatrics Department of Pathology Medical Department A and Department of Clinical Chemistry University Hospital Rikshospitalet Oslo Norway

ABSTRACT Henriksen N T Langmark F Sørland S J Fausa O Landaas S and Aagenaes O (Department of Paediatrics Department of Pathology Medical Department A and Department of Clinical Chemistry University Hospital Rikshospitalet Oslo Norway) Hereditary cholestasic combined with peripheral pulmonary stenosi and other anomalies. Acta Paediatr Scand 66 7 1977.—A syndrome consisting of chronic intrahepatic cholestasis with retention of bile acids but with normalization of bile pigment excretion and blood lipids peripheral pulmonary stenosis vertebral anomalies and a characteristic facies is described in six patients including a father and his daughter An autosomal dominant mode of inheritance is suggested

KEY WORDS Intrahepatic cholestasis retention of bile acids peripheral pulmonary stenosis vertebral anomalies characteristic facies autosomal inheritance

In 1970 Alagille & Thomassin (1) presented 25 children with chronic intrahepatic cholestasis with constant or intermittent jaundice severe itching and hepatomegaly A characteristic facies was noted in some of them and in some a stenotic systolic cardiac murmur was heard In many of the patients there was found a partial absence of the intrahepatic interlobular bile ducts Later Watson & Miller (16) described a syndrome with the following salient features 1) congenital hypoplasia with stenosis of the main pulmonary arteries 2) neonatal liver disease with cholestasis and 3) various minor congenital anomalies including an odd facies Recently Alagille et al (2) reported that intrahepatic hypoplasia of the bile ducts was the main hepatic morhpological feature of the syndrome Other striking features were characteristic facies vertebral malformations retarded physical mental and sexual development and cardiac murmur

At the Paediatric Department Rikshospitalet National Hospital of Norway Oslo we have studied this syndrome in 6 patients including a father and his daughter

LABORATORY METHODS

The enzyme concentrations in serum have been determined over a period of 12 years and different methods have therefore been applied The following method numbers correspond to the index numbers in Table 3 where the reference intervals for adults are also shown for each method Alkaline phosphatase alanine aminotransferase (ALAT) and aspartate aminotransferase (ASAT) (methods 2 4 and 6 respectively) are today measured on the basis of the methods recommended by the Scandinavian Committee on Enzymes Alkaline phosphatase was earlier determined (method 1) by the method applied by Bessey & Lowry (?5?) and the transaminases (methods 3 and 5) by the method of Reitman & Frankel (37?) Ornithine carbamyl transferase (OCT) (methods 7 and 8) has been measured by two different modifications of the isotope method of Reichard (37?)

The serum levels of cholesterol were determined photometrically by the Liebermann Burchard reaction and triglycerides by the method of Laurell

Scandinavian countries We hope that this Scandinavian collaboration will develop and become consolidated

Let me end this short expose with two quotations one by Rene Dubos, the other by John Apley

La santé est une potentialité l aptitude de l individu ou du groupe social à se modifier sans cesse non seulement pour mieux fonctionner dans le présent mais aussi pour se préparer à l avenir

The most important question mankind can ask itself is When our children grow up what sort of adults and parents will they be? To find answers and to help them and their children in turn we must study the psychosocial milieu And we should constantly remind ourselves that *all childhood is a critical period*

HEREDITARY CHOLESTASIS COMBINED WITH PERIPHERAL PULMONARY STENOSIS AND OTHER ANOMALIES

N T HENRIKSEN F LANGMARK S J SØRLAND O FAUSA
S LANDAAS and Ø AAGENAES

From the Department of Paediatrics Department of Pathology Medical Department A and Department of Clinical Chemistry University Hospital Rikshospitalet Oslo Norway

ABSTRACT Henriksen N T Langmark F Sørland S J Fausa O Landaas S and Aagenaes O (Department of Paediatrics Department of Pathology Medical Department A and Department of Clinical Chemistry University Hospital Rikshospitalet Oslo Norway) Hereditary cholestasis combined with peripheral pulmonary stenosis and other anomalies Acta Paediatr Scand 66 7 1977.—A syndrome consisting of chronic intrahepatic cholestasis with retention of bile acids but with normalization of bile pigment excretion and blood lipids peripheral pulmonary stenosis vertebral anomalies and a characteristic facies is described in six patients including a father and his daughter An autosomal dominant mode of inheritance is suggested

KEY WORDS Intrahepatic cholestasis retention of bile acids peripheral pulmonary stenosis vertebral anomalies characteristic facies autosomal inheritance

In 1970 Alagille & Thomassin (1) presented 25 children with chronic intrahepatic cholestasis with constant or intermittent jaundice severe itching and hepatomegaly A characteristic facies was noted in some of them and in some a stenotic systolic cardiac murmur was heard In many of the patients there was found a partial absence of the intrahepatic interlobular bile ducts Later Watson & Miller (16) described a syndrome with the following salient features 1) congenital hypoplasia with stenosis of the main pulmonary arteries 2) neonatal liver disease with cholestasis and 3) various minor congenital anomalies including an odd facies Recently Alagille et al (2) reported that intrahepatic hypoplasia of the bile ducts was the main hepatic morhpological feature of the syndrome Other striking features were characteristic facies vertebral malformations retarded physical mental and sexual development and cardiac murmur

At the Paediatric Department Rikshospitalet National Hospital of Norway Oslo we have studied this syndrome in 6 patients including a father and his daughter

LABORATORY METHODS

The enzyme concentrations in serum have been determined over a period of 1? years and different methods have therefore been applied The following method numbers correspond to the index numbers in Table 3 where the reference intervals for adults are also shown for each method Alkaline phosphatase alanine aminotransferase (ALAT) and aspartate aminotransferase (ASAT) (methods 2 4 and 6 respectively) are today measured on the basis of the methods recommended by the Scandinavian Committee on Enzymes Alkaline phosphatase was earlier determined (method 1) by the method applied by Bessey & Lowry (25°) and the transaminases (methods 3 and 5) by the method of Reitman & Frankel (37°) Ornithine carbamyl transferase (OCT) (methods 7 and 8) has been measured by two different modifications of the isotope method of Reichard (37°)

The serum levels of cholesterol were determined photometrically by the Liebermann Burchard reaction and triglycerides by the method of Laurell

Scandinavian countries We hope that this Scandinavian collaboration will develop and become consolidated

Let me end this short expose with two quotations, one by Rene Dubos the other by John Apley

La santé est une potentialité l aptitude de l individu ou du groupe social à se modifier sans cesse non seulement pour mieux fonctionner dans le présent mais aussi pour *se préparer à l avenir*

The most important question mankind can ask itself is When our children grow up what sort of adults and parents will they be? To find answers and to help them and their children in turn we must study the psychosocial milieu And we should constantly remind ourselves that *all childhood is a critical period*

ALAT and ASAT) except in A H when she was a neonate

The cholesterol concentration early in infancy was determined in only one patient (C H) A moderate increase was found Later in childhood it was even more increased but now there is no hyperlipemia Similarly the two youngest patients (3 and 3½ years old) have hyperlipemia while the other older patients have normal lipid concentration in relation to age

The serum concentrations of total bile acids (Table 3) are increased in all the patients except one and in some of them the values are very high Bile acid separation has shown no unusual bile acids (Prof Eyssen)

Liver biopsies Table 4 shows that altogether 12 biopsies were taken from the six patients The main morphological criterion for the diagnosis is lack or paucity of bile ducts in the portal areas One patient had a completely normal liver biopsy (needle) In the other patients the number of portal areas containing bile ducts varied from 0 to 50% of the total Bile stasis with bile plugs in the bile capillaries and accumulation of bile pigment in

The bile acids shown in Table 3 were determined by the method described by Fausa (10) the upper normal limit is considered to be 6 mmol/l

Gas liquid chromatography of bile acids was performed by Prof H Eyssen Brussels

The endocrinologic analyses were carried out by the Hormone and Isotope Laboratory Aker Hospital Oslo

RESULTS

Table 1 and 2 show the clinical course in the patients They were small for date at birth with an average birth length of 47 cm All the patients except one of the boys (J H) have a history of neonatal cholestasis Exploratory laparotomy was performed in three and they have normal extrahepatic bile ducts The liver was enlarged in all the patients except in the nonicteric boy (J H)

Jaundice was of short duration in most of the patients while pruritus continued for a long time and still persists in two of the boys 11 and 12 years old Following the disappearance of jaundice, the liver size became normal Steatorrhea was constant during the severe cholestatic period in infancy but then gradually improved Only one girl (A H) still has steatorrhea Table 3 shows the biochemical changes in our patients The bilirubin concentration was increased during the neonatal period (and also later in infancy) but the values are now below the upper normal limit in all the patients except A H With regard to the liver enzymes OCT is increased in all the patients The serum concentrations of alkaline phosphatase is normally much higher in children and especially in infants than in adults and all the neonatal values are within the normal range for this age group However the alkaline phosphatase levels are at present increased The concentrations of the two transaminases are increased in relation to age in all patients (2–4 times upper normal limit for both

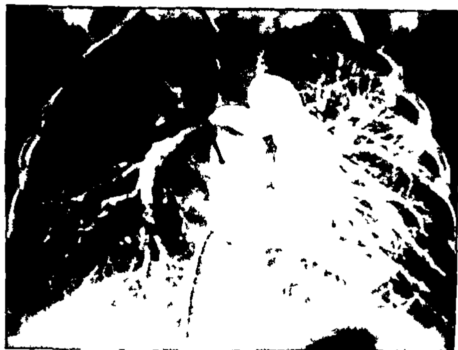

Fig 1 Stenosis of the right pulmonary artery (arrow) in one of the patients (A K R)

the hepatocytes was a prominent feature in biopsies taken during the first 12 months of life confirming the clinical and biochemical findings In these biopsies a variable degree of inflammatory reaction with granulocytes and lymphocytes in the portal areas was also found frequently together with swollen and granulated hepatocytes In older patients no pathological liver findings were seen at light microscopy except lack of ducts in a variable number of portas areas In the case with the most severe clinical history (A H) the liver also revealed the most severe changes with increasing fibrosis from the second year of life None of the biopsies showed giant cell transformation

Cardiac findings All the patients have a systolic cardiac murmur and the results of the cardiac examinations are presented in Table 5 The murmur is shown by catheterisation to be caused by stenoses in the great pulmonary arteries There were no other cardiac anomalies The stenoses were located on different site in the peripheral pulmonary tree with the gradient over the stenoses ranging from 10 to 35 mm Fig 1 shows stenosis on the right side in the main pulmonary vessel in one of the patients (A K R) None of the patients has cardiac symptoms

Facies A characteristic facies is present in all (Figs 2 3 and 4) There are slight hypertelorism the eyes are deeply set the chin

Clinical diagnosis PPS

Fig 2 One of the patients (A H) in infancy

Fig 4 One of the patients (T O) 11 years old

Fig 3 Another patient (C H) in infancy

bones are wide apart and the forehead is broad The profile is flat

Vertebrae Most of the patients have verte bral anomalies (Table 2) and these are of dif ferent kinds hemivertebra cleft in the verte bral body unsegmented body wedgeshaped body and in one patient spina bifida oculta

Growth Three children were growth re tarded two of them transiently while one still is (Table 2) The growth curve of one of them (C H) (Fig 5) is at the 2 5 percentile at 2 years and 50 percentile at 10 years

Mental development Only one child is re tarded (Table 2)

Endocrinological examinations The hor mone analyses including T4 PBI daily excre tion of 17 ketogenic steroids cortisol in se rum FSH LH TSH and HGH were all nor mal except extremely high values for the growth hormone in the severely retarded girl (A H) (Table 2) The size of the testes in our three prepubertal boys is normal Testoster

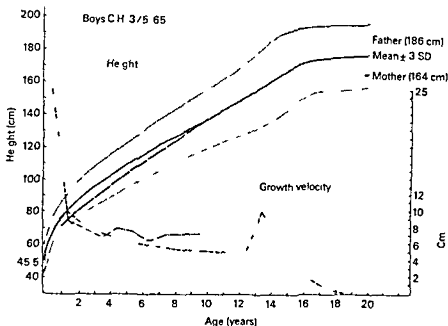

Fig 5 Growth curve and growth velocity curve in one of the pre pubertal boys (C H)

one measured before and after choriongonado tropin stimulation showed normal values (performed in only two of the three boys)

Family observations (Fig 6) The father and a younger sister of one patient (J H) have a systolic murmur probably caused by periph eral pulmonary stenosis The father of one of the others (A H) has a similar cardiac mur mur The five children have altogether five siblings Aside from the father included in our study there is no evidence of liver disease in the family members

Other examinations Examinations for an infectious etiology of the liver disease have been negative Alfa 1 antitrypsin levels are within normal limits Chromosome analyses performed in five of the patients are normal

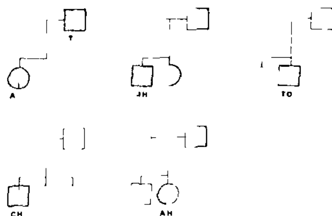

Fig 6 The parents and their children in the affected families Vertical lines=cholestasis Horizontal lines= peripheral pulmonary stenosis

DISCUSSION

The liver disease The clinical picture in our patients is dominated by the liver disease most often presenting as a neonatal cholesta sis The most prominent symptom is itching persisting for many years after the jaundice disappeared and the bilirubin became normal One patient was not jaundiced at all Itching in liver or biliary disease is thought to be caused by retention of bile salts Most often they are retained together with the bile pig ments because of obstruction in the common excretion pathways resulting in the well known combination of jaundice and pruritus It is however a well established fact that the excretory mechanisms for bile acids are not the same as for bilirubin Norman & Strandvik (14) found disturbed excretion of bile acids and elevated serum transaminases for up to more than a year after the disappearance of jaun dice in a number of patients who had intra hepatic cholestasis in infancy In a patient with the disorder known as benign recurrent intrahepatic cholestasis (3) the serum bile acids were found to be considerably increased without an initial increase of bilirubin The

laboratory analyses (Table 3) show the dis sociation between the secretion of bile acids and of bilirubin in our patients The levels of serum bile acids are variously elevated from borderline to very high values while bilirubin levels have become normal in all patients ex cept one

There seems to exist only partial correla tion between the serum bile acid levels and the itching in our patients However as stated by Luders (13) it has not been proven that the total bile acids or any bile acid at all are di rectly responsible for the itching Perhaps an unknown substance is retained together with the bile acids On the other hand Luders emphasizes the importance of disturbed bile acid metabolism in the pathogenesis of liver damage with cholestasis

Disturbances of the bile acid metabolism have been shown (9 11) to be connected with a familial form of childhood cholestasis with hypoplasia of the intrahepatic bile ductules It was found high amounts of trihydroxyco prostanic acid in duodenal fluid as a result of defective conversion of this natural precursor to cholic acid in the liver cells In the patients of Eyssen et al (9) the metabolic acid defect was also connected with a number of congeni tal anomalies In our patients we have not found any unusual bile acid either in serum or in duodenal fluid which could point to a specific metabolic defect

The disappearance of steatorrhea suggests that the intestinal function of the bile acids is not severely affected and this suggestion was supported by the bile acid analyses in the dou denal fluid in two of the patients

Surprisingly enough we have not found that cholestyramine has had any convincing effect on the itching However the doses may not have been high enough or it may not have been taken in the prescribed way We have tried phenobarbital which is reported to have an effect on itching probably due to enzyme induction in the liver (15) There has been a clinical effect but no normalization of the pathological biochemical findings so far

The elevated levels of liver enzymes in serum are in accordance with a liver disorder involving both cell damage and a moderate cholestasis The normal values of alkaline phosphatase neonatally are probably due to the fact that isoenzymes originating from the bone will mask any elevation of liver enzymes if it is not very severe

Hyperlipemia has been present in the younger age group but not in the older pa tients

The pathological findings in the liver biop sies taken from the infants with this condition are not specific In only one of the twelve biopsies was the lack of bile ducts mentioned in the primary description but portal inflam mation frequently obscures the anatomical features (5) and makes the ducts hard to find particularly in needle biopsies in which portal areas may be insufficient in number for ade quate examination (six is considered a mini mum for being representative) Moreover there may be artefactual loss of whole portal areas for technical reasons

The diagnostic finding is paucity of bile ducts (4) Those which are present do not give any clue as to pathogenesis They look normal without signs of degeneration in flammation or obliteration but this may some times be difficult to judge in the icteric state because of the presence of general portal in flammation In older patients in the anicteric state the portal areas were completely normal with regard to number and size of portal ves sels No trace of bile duct disease was seen in areas devoid of ducts not even concentric fibrosis which is otherwise quite frequently seen in disuse atrophy of vessels where the scar tissue to some degree imitates the size and structure of the vanished vessel In many ways the patients with this syndrome do not seem to fit the concepts of Landing (12) on neonatal cholestasis and infantile obstructive cholangiopathy Studies on bile acid metab olism and transport in the liver may be more fundamental to the understanding of this dis ease

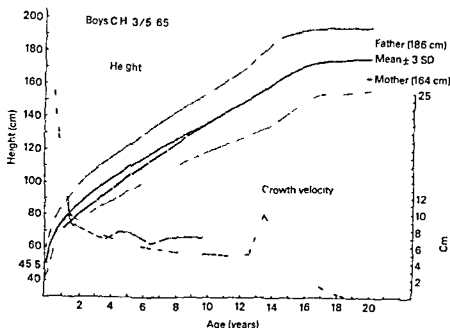

Fig 5 Growth curve and growth velocity curve in one of the pre pubertal boys (C H)

one measured before and after choriongonado tropin stimulation showed normal values (performed in only two of the three boys)

Family observations (Fig 6) The father and a younger sister of one patient (J H) have a systolic murmur probably caused by periph eral pulmonary stenosis The father of one of the others (A H) has a similar cardiac mur mur The five children have altogether five siblings Aside from the father included in our study there is no evidence of liver disease in the family members

Other examinations Examinations for an infectious etiology of the liver disease have been negative Alfa 1 antitrypsin levels are within normal limits Chromosome analyses performed in five of the patients are normal

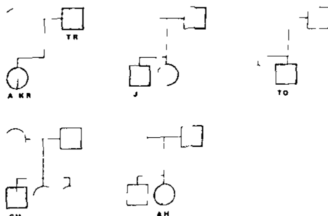

Fig 6 The parents and their children in the affected families Vertical lines=cholestasis Horizontal lines= peripheral pulmonary stenosis

DISCUSSION

The liver disease The clinical picture in our patients is dominated by the liver disease most often presenting as a neonatal cholesta sis The most prominent symptom is itching persisting for many years after the jaundice disappeared and the bilirubin became normal One patient was not jaundiced at all Itching in liver or biliary disease is thought to be caused by retention of bile salts Most often they are retained together with the bile pig ments because of obstruction in the common excretion pathways resulting in the well known combination of jaundice and pruritus It is however a well established fact that the excretory mechanisms for bile acids are not the same as for bilirubin Norman & Strandvik (14) found disturbed excretion of bile acids and elevated serum transaminases for up to more than a year after the disappearance of jaun dice in a number of patients who had intra hepatic cholestasis in infancy In a patient with the disorder known as benign recurrent intrahepatic cholestasis (3) the serum bile acids were found to be considerably increased without an initial increase of bilirubin The

The syndrome has been observed in 5 unrelated families living in or around Oslo Accordingly it does not seem to be rare and one should bear it in mind in patients with neonatal cholestasis and in patients with unexplained itching The syndrome is of great theoretical interest and may provide valuable information about metabolism and transport of bile acids in infants as well as adults

ACKNOWLEDGEMENT

We would like to thank Professor H Eyssen Brussels Belgium for performing bile acid agas liquid chromatography

Peripheral pulmonary stenosis This means a stenosis of the great pulmonary arteries pe ripheral to the valves Isolated it has hitherto been considered a rather rare defect It is thought to be nonprogressive (8) and there is a tendency to familial occurrence In Norway a family has been described (6) in which it was either isolated or associated with coarctation of the aorta It was shown that this condition was one of the few congenital heart diseases in which one single gene probably autosomal dominant was operative All our patients and probably two of the fathers and one sibling have isolated peripheral pulmonary stenosis

Facies Our patients as well as the others reported resemble each other like siblings This however, is not uncommon in congenital syndromes

Vertebral anomalies are frequent and of different types For the most part only one anomaly is present in each patient and it seems to be without clinical significance Ala gille et al (2) however related the growth retardation in their patients to vertebral anom alies mostly spina bifida defects

Growth retardation Two of our patients are in the lower range of normal height (2 5 to 10 percentile) and one is markedly retarded One patient had a cath up growth during a 10 year period (Fig 5) and during the same period his liver disease showed a definite improvement The markedly growth retarded patient (A H) is the one with the most severe liver disease She is our only patient without a vertebral anomaly One of the boys (J H) has during two years observation shown a small catch up growth from 2 5 towards 10 percentile These findings seem to indicate that the growth re tardation is directly related to the degree and duration of liver dysfunction and that there is no correlation between vertebral anomalies and growth retardation in our patients

Courtecuisse et al (7) reported extremely high concentrations of growth hormone in their growth retarded patients with hepatic ductular hypoplasia Our finding in the re tarded patient with a growth hormone level usually found in acromegalic patients is thus in accordance with the findings of the French workers The levels in our other patients were within normal range

Mentally our patients are normal except one of the girls (A H) The three schoolchildren manage their schoolwork well Alagille et al (2) found a moderate mental retardation (IQ 60–80) in 9 out of 15 patients This and other observations which differ from ours may be due to different methods of patient selection the French patients are all from a special pediatric liver unit and are probably more af fected by their liver disease than our patients

Gonadal function Clinical and hormonal examinations have not shown signs of hypo gonadism The fact that there among our pa tients is a father and his child also points against severe hypogonadism

Genetic aspect The family data are pre sented in Fig 6 which shows the mode of transmission of the disease Three of the fathers are probably affected by peripheral pulmonary stenosis and one also by the liver disease These observations taken with the 1 1 ratio of affected to unaffected children suggest an autosomal dominant genetic basis for the disorder This interpretation is in ac cordance with other observations on this syn drome (16)

CONCLUSION

Our 6 patients fit very well with the syndrome called arteriohepatic dysplasia by Watson & Miller (16) One main feature is a liver dis ease which usually starts as a neonatal chole stasis and after a time manifests itself as a chronic partial cholestasis with pruritus and increased levels of bile acids and liver en zymes but with normal bilirubin concentra tion We feel that the dysfunction primarily is caused by a defect in the metabolism or trans port of bile acids in the liver cells or bile cana liculi Long term observations indicate that the prognosis is quite good The other features of the syndrome are characteristic

SKIM MILK IN INFANT FEEDING

S J FOMON L J FILER JR E E ZIEGLER K E BERGMANN
and R L BERGMANN

*From the Department of Pediatrics College of Medicine University of Iowa
Iowa City Iowa USA*

ABSTRACT Fomon S J Filer L J Jr Ziegler E E Bergmann K E and Bergmann R L (Department of Pediatrics College of Medicine University of Iowa Iowa City Iowa 52242) Skim milk in infant feeding Acta Paediatr Scand 66 17 1977.—Ninety four infants were enrolled at 112 days of age in a study of food intake and growth and 88 were considered to have completed satisfactorily the planned 56 days of observation The infants lived at home Feedings consisted of a commercially available formula (Similac 67 kcal/100 ml) or a slightly modified skim milk (Formula 305 36 kcal/100 ml) and commercially prepared strained foods Energy intake and gain in weight were significantly greater by infants fed Similac than by those fed Formula 305 Gain in length was nearly identical in the two feeding groups During the 56 days of observation triceps and subscapular skin fold thicknesses changed little in infants fed Similac but decreased approximately 25% in infants fed Formula 305 It is suggested that body fat stores of infants fed Formula 305 were mobilized to permit growth of fat free tissue

KEY WORDS Skim milk infant feeding body fat depletion

From the 1940s until the mid 1960s the majority of infants in the United States were fed evaporated milk formulas or commercially prepared formulas from birth until 4 to 6 months of age and were then fed homogenized whole cow milk (1) Although data on the percentages of infants fed milk of reduced fat content are lacking it appears that in the 1970s an appreciable percentage of infants are fed skim milk or 2% milk [1] beginning at 4 to 6 months of age Reasons given by parents and physicians for use of milk of reduced fat content seem to relate primarily to the hypothesis that the overfed infant is destined to become the obese adult Thus a feeding of decreased caloric density is employed (1) as a reducing diet for an infant who is (or is believed to be) obese or (2) for the prevention of obesity Finally at least some parents and physicians appear to believe that dietary measures aimed at prevention of atherosclerosis (i e reduction in intake of cholesterol and saturated fatty acids) should be instituted as early in life as possible and therefore prefer skim to whole milk during infancy

Several theoretic considerations suggested that skim cow milk might not be as satisfactory as whole cow milk for infant feeding These will be discussed subsequently (see Discussion) Yet the absence of data on food consumption and growth of infants fed skim milk made it impossible to do more than speculate about the results of such feeding We therefore attempted to design a set of circumstances that would permit accumulation of the desired information without risk to the infant subjects Subjects known to be healthy and to be grow

length and weight were corrected by parabolic inter polation or extrapolation utilizing three consecutive values to yield data applicable to exact ages Values applicable to 11[illegible] days were corrected using values from measurements at 84 and 140 days those applicable to 140 days were corrected using values from 11[illegible] and 168 days and those applicable to 168 days were corrected using values from 11[illegible] and 140 days

In the second study triceps and subscapular skinfold thicknesses were also measured Measurements were made as described by Fomon ([illegible]6) with the following modifications the infant was held on the mother s lap with right side adjacent to but not touching the mother s trunk the infant s left elbow was flexed 90° and the fore arm held gently against the infant s abdomen readings were made to the nearest 0 1 mm Two trained examiners measured skinfold thickness at each site three times the average of the six measurements was utilized The mean difference between examiners in measurement of triceps skinfold thickness was 0 56 mm and the standard deviation of the difference was 0 60 mm The corresponding mean difference for subscapular skinfold measurements was 0 46 mm and the standard deviation of the difference was 0 50 mm Skinfold measurements were corrected by simple linear interpolation or extrapolation using the two values closest to the desired age

RESULTS

Data concerning all infants enrolled in the study are presented in the Appendices Pre liminary analyses of the results indicated that until eliminated from the study performance of the 6 infants who failed to complete the planned period of 56 days of observation in a satisfactory manner was similar to that of the remainder of the subjects The presentation that follows concerns the 88 infants for whom complete data are available A summary of the data is presented in Table 2 Data on length and weight of individual infants are presented in Appendix I data on skinfold thicknesses are presented in Appendix II and detailed data on food intake are presented in Appendix III

Food consumption

In both studies infants fed Formula 305 con sumed greater quantities of formula than did infants fed Similac For the age interval 112 through 167 days the difference was signifi cant for males in the first study ($p<0\ 01$) and for males and females in the second study ($p<0\ 001$) Despite the greater volumes con sumed energy intake from formula by infants fed Formula 305 was less than that by infants fed Similac In each study the difference was significant ($p<0\ 001$)

Infants fed Formula 305 consumed some what greater quantities of beikost than did in fants fed Similac but the difference was not significant in either study The greater con sumption of beikost by infants fed Formula 305 was not sufficient to offset the lower in take of energy from formula Thus for infants of the same sex total energy intake in each study was significantly less for infants fed Formula 305 than for those fed Similac ($p<0\ 001$)

As in previous studies of younger infants (7) males consumed greater quantities of food than did females In the second study reported here (in which both sexes were included) total food consumption (formula and beikost) was significantly greater ($p<0\ 01$) by males than

ing normally were fed skim milk for a period of 56 days (112 through 167 days of age)

Two separate studies were carried out In both studies, performance of infants fed a slightly modified skim milk was compared with that of infants fed a commercially prepared formula (Similac with Iron[1]) Measurements included food intake and gain in length and weight The second study included in addition measurements of triceps and subscapular skinfold thickness

SUBJECTS

The infant subjects were mainly children of faculty or students in the University All had been enrolled in feeding studies from 8 through 111 days of age During that period three infants (nos 1079 1080 and 1094) had been breastfed and were managed as described previously (4) Two infants (1659 and 1660) fed a milk based formula had served as subjects in balance studies conducted in the manner described in detail elsewhere (2*a*) All other infants had received milk based or soy isolate based formulas providing 67 kcal/100 ml Details of management of formula fed infants have been described in previous publications (5-7)

Appendix I provides data on birth date weight at birth and body weight and length at age 112 days—the time of enrollment in the study described here With few exceptions available infants of the same sex were enrolled alternately by date of birth into the two feeding groups In every case the plan of study was reviewed in detail with one or both parents and written permission was obtained [2]

The studies were planned to permit 56 days of observation of each of 14 or 15 infants in each of the following feeding groups in the first study (infants born between June 18 1971 and August 30 1972) males fed Formula 305 (i e modified skim milk see Feedings) and Similac in the second study (infants born between December 28 1972 and September 14 1974) males and females fed Formula 305 and males and females fed Similac Additional infants were enrolled to replace dropouts so that in each feeding group at least 14 subjects would complete the 56 days of observation In only one group did it prove necessary to enroll more than 16 infants

Ninety four infants were enrolled and 88 were considered to have completed the planned 56 days of observation (112 through 167 days) in a satisfactory manner One male infant (1606) fed Similac was eliminated from the study after 140 days of age because it proved impossible for the authors to obtain daily weights of food consumed Another male infant (1805) fed Similac was withdrawn from study before 140 days of age because of diarrhea Two female infants fed Formula 305 were excluded before the appointment scheduled for 168 days of age one (1869) having had the feeding changed to whole cow milk and the other (1826) having been fed a soy isolate formula In neither case was the reason for the change in diet known Two infants (1782 and 1823) failed to be measured between 164 and 172 days of age (see Procedures and Methods) and were therefore considered incomplete Among the 88 infants considered to have completed the study in a satisfactory manner three (1802 2106 2122 see Appendix I) failed to be measured between 136 and 144 days of age

FEEDINGS

Table I presents the composition of the formulas fed during the first and second study It should be noted that Formula 305 is identical to skim milk except for the addition of fat soluble vitamins and a sufficient quantity of safflower oil (0 23 g/100 ml) to assure an adequate intake of linoleic acid Infants fed Formula 305 received a daily supplement providing 15 mg of iron in the form of ferrous sulfate [3] Each formula was supplied in quart cans of known gross weight A supply of formula was delivered to the family and empty partially empty or full cans were collected from the family at the time of the next delivery The returned cans were weighed to determine the quantity of formula consumed From the composition of the formula (Table I) and the quantity of formula consumed the intake of calories was calculated

Commercially prepared strained foods produced by one manufacturer[4] were permitted without restriction of variety or amount Because the infants received medical care from private practitioners in Iowa City or nearby communities or from physicians (mainly house officers) in the Child Health Clinic of the Department of Pediatrics University of Iowa a wide variety of attitudes relating to feeding of beikost (i e foods other than milk or formula) was represented Jars of beikost were purchased by the parents and the empty or partially empty jars were collected by the milk delivery team Utilizing the manufacturer s published analyses (10) the intake of calories and specific nutrients contributed by beikost could be calculated

PROCEDURES AND METHODS

With the exceptions noted previously (see Subjects) weight and length of each infant was measured as described previously (2*b*) within 4 days of each of the following ages 112 140 and 168 days Measurements of

length and weight were corrected by parabolic interpolation or extrapolation utilizing three consecutive values to yield data applicable to exact ages Values applicable to 112 days were corrected using values from measurements at 84 and 140 days those applicable to 140 days were corrected using values from 112 and 168 days and those applicable to 168 days were corrected using values from 112 and 140 days

In the second study triceps and subscapular skinfold thicknesses were also measured Measurements were made as described by Fomon (*b*) with the following modifications the infant was held on the mother s lap with right side adjacent to but not touching the mother s trunk the infant s left elbow was flexed 90 and the fore arm held gently against the infant s abdomen readings were made to the nearest 0 1 mm Two trained examiners measured skinfold thickness at each site three times the average of the six measurements was utilized The mean difference between examiners in measurement of triceps skinfold thickness was 0 56 mm and the standard deviation of the difference was 0 60 mm The corresponding mean difference for subscapular skinfold measurements was 0 46 mm and the standard deviation of the difference was 0 50 mm Skinfold measurements were corrected by simple linear interpolation or extrapolation using the two values closest to the desired age

RESULTS

Data concerning all infants enrolled in the study are presented in the Appendices Preliminary analyses of the results indicated that until eliminated from the study performance of the 6 infants who failed to complete the planned period of 56 days of observation in a satisfactory manner was similar to that of the remainder of the subjects The presentation that follows concerns the 88 infants for whom complete data are available A summary of the data is presented in Table 2 Data on length and weight of individual infants are presented in Appendix I data on skinfold thicknesses are presented in Appendix II and detailed data on food intake are presented in Appendix III

Food consumption

In both studies infants fed Formula 305 consumed greater quantities of formula than did infants fed Similac For the age interval 112 through 167 days the difference was significant for males in the first study ($p<0\ 01$) and for males and females in the second study ($p<0\ 001$) Despite the greater volumes consumed energy intake from formula by infants fed Formula 305 was less than that by infants fed Similac In each study the difference was significant ($p<0\ 001$)

Infants fed Formula 305 consumed somewhat greater quantities of beikost than did infants fed Similac but the difference was not significant in either study The greater consumption of beikost by infants fed Formula 305 was not sufficient to offset the lower intake of energy from formula Thus for infants of the same sex total energy intake in each study was significantly less for infants fed Formula 305 than for those fed Similac ($p<0\ 001$)

As in previous studies of younger infants (7) males consumed greater quantities of food than did females In the second study reported here (in which both sexes were included) total food consumption (formula and beikost) was significantly greater ($p<0\ 01$) by males than

ing normally were fed skim milk for a period of 56 days (112 through 167 days of age)

Two separate studies were carried out In both studies performance of infants fed a slightly modified skim milk was compared with that of infants fed a commercially prepared formula (Similac with Iron[1]) Measurements included food intake and gain in length and weight The second study included in addition measurements of triceps and subscapular skinfold thickness

SUBJECTS

The infant subjects were mainly children of faculty or students in the University All had been enrolled in feeding studies from 8 through 111 days of age During that period three infants (nos 1079 1080 and 1094) had been breastfed and were managed as described previously (4) Two infants (1659 and 1660) fed a milk-based formula had served as subjects in balance studies conducted in the manner described in detail elsewhere (2*a*) All other infants had received milk based or soy isolate based formulas providing 67 kcal/100 ml Details of management of formula fed infants have been described in previous publications (5–7)

Appendix I provides data on birth date weight at birth and body weight and length at age 112 days—the time of enrollment in the study described here With few exceptions available infants of the same sex were enrolled alternately by date of birth into the two feeding groups In every case the plan of study was reviewed in detail with one or both parents and written permission was obtained [2]

The studies were planned to permit 56 days of observation of each of 14 or 15 infants in each of the following feeding groups in the first study (infants born between June 18 1971 and August 30 1972) males fed Formula 305 (i e modified skim milk see Feedings) and Similac in the second study (infants born between December 28 1972 and September 14 1974) males and females fed Formula 305 and males and females fed Similac Additional infants were enrolled to replace dropouts so that in each feeding group at least 14 subjects would complete the 56 days of observation In only one group did it prove necessary to enroll more than 16 infants

Ninety four infants were enrolled and 88 were considered to have completed the planned 56 days of observation (112 through 167 days) in a satisfactory manner

One male infant (1606) fed Similac was eliminated from the study after 140 days of age because it proved impossible for the authors to obtain daily weights of food consumed Another male infant (1805) fed Similac was withdrawn from study before 140 days of age because of diarrhea Two female infants fed Formula 305 were excluded before the appointment scheduled for 168 days of age one (1869) having had the feeding changed to whole cow milk and the other (1826) having been fed a soy isolate formula In neither case was the reason for the change in diet known Two infants (1782 and 1823) failed to be measured between 164 and 172 days of age (see Procedures and Methods) and were therefore considered incomplete Among the 88 infants considered to have completed the study in a satisfactory manner three (1802 2106 2122 see Appendix I) failed to be measured between 136 and 144 days of age

FEEDINGS

Table 1 presents the composition of the formulas fed during the first and second study It should be noted that Formula 305 is identical to skim milk except for the addition of fat soluble vitamins and a sufficient quantity of safflower oil (0 23 g/100 ml) to assure an adequate intake of linoleic acid Infants fed Formula 305 received a daily supplement providing 15 mg of iron in the form of ferrous sulfate [3] Each formula was supplied in quart cans of known gross weight A supply of formula was delivered to the family and empty partially empty or full cans were collected from the family at the time of the next delivery The returned cans were weighed to determine the quantity of formula consumed From the composition of the formula (Table 1) and the quantity of formula consumed the intake of calories was calculated

Commercially prepared strained foods produced by one manufacturer[4] were permitted without restriction of variety or amount Because the infants received medical care from private practitioners in Iowa City or nearby communities or from physicians (mainly house officers) in the Child Health Clinic of the Department of Pediatrics University of Iowa a wide variety of attitudes relating to feeding of beikost (i e foods other than milk or formula) was represented Jars of beikost were purchased by the parents and the empty or partially empty jars were collected by the milk delivery team Utilizing the manufacturer s published analyses (10) the intake of calories and specific nutrients contributed by beikost could be calculated

PROCEDURES AND METHODS

With the exceptions noted previously (see Subjects) weight and length of each infant was measured as described previously (2*b*) within 4 days of each of the following ages 112 140 and 168 days Measurements of

[1] Ross Laboratories Columbus Ohio Throughout the text each reference to Similac applies to Similac with Iron

[4] Gerber Products Company Fremont Michigan

by females fed Similac During the age interval 112 through 167 days total energy intake by infants fed Similac was 681 kcal/day (96 8 kcal/kg/day) for males and 609 kcal/day (94 2 kcal/kg/day) for females When energy intake was expressed as kcal/day but not when it was expressed as kcal/kg/day the difference between males and females was significant ($p<0\ 01$) Lesser sex related differences in food intake existed in the second study among infants fed Formula 305 these differences did not reach statistical significance

Of some interest is the lesser intake of beikost in the second than in the first study Average intakes by male infants fed Formula 305 and Similac in the first study averaged 304 and 248 g/day respectively Corresponding intakes in the second study were 214 and 197 g/day The explanation of this difference is uncertain but it may be attributable at least in part to general changes in attitudes in the community toward early introduction and extensive feeding of beikost

Gain in weight and length

Gain in weight was significantly less ($p<0\ 01$) by male and female infants fed Formula 305 than by those fed Similac (Table 2) During the interval 112 through 167 days of age gain in weight by infants fed Formula 305 averaged for males 13 4 g/day in the first study and 11 4 g/day in the second study gain in weight by females (second study) averaged 11 3 g/day Corresponding values for infants fed Similac were 18 1 19 3 and 16 1 g/day

Gain in weight per unit of energy intake (Table 2) was less by infants fed Formula 305 than by those fed Similac but the difference was significant ($p<0\ 02$) only in male infants in the second study A significant feeding related difference in gain in length was not demonstrated

Skinfold thickness

As previously mentioned skinfold thickness was measured only in the second study At the time of enrollment in the study (age 112 days)

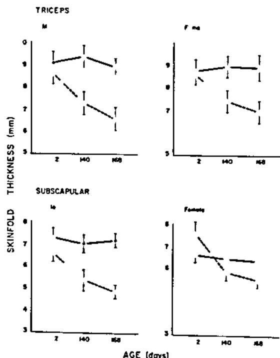

Fig 1 Triceps and subscapular skinfold thicknesses at various ages in relation to feeding by infants fed Similac (solid line) or Formula 305 (interrupted line) Formula 305 was a slightly modified skim milk with low caloric density At each age the mean and plus or minus one standard error of the mean are indicated

mean triceps skinfold thickness of males who were to be fed Formula 305 was 8 61 mm and that of males to be fed Similac was 9 08 mm This difference is not statistically significant ($p>0\ 05$) Corresponding values for mean subscapular skinfold thickness of males were 6 61 and 7 29 mm The difference is not statistically significant Similarly for females there was no statistically significant difference in mean triceps or subscapular skinfold thickness between the two groups at the time of enrollment Data on skinfold thickness of individual infants at various ages are presented in Appendix II

As may be seen from Fig 1 little change in skinfold thickness of infants fed Similac occurred between 112 and 168 days of age By contrast among male infants fed Formula 305 mean triceps skinfold thickness decreased 2 05 mm (an amount equal to 24% of the initial value) and mean subscapular skinfold thick

by females fed Similac During the age interval 112 through 167 days total energy intake by infants fed Similac was 681 kcal/day (96 8 kcal/kg/day) for males and 609 kcal/day (94 2 kcal/kg/day) for females When energy intake was expressed as kcal/day but not when it was expressed as kcal/kg/day the difference between males and females was significant ($p<0\ 01$) Lesser sex related differences in food intake existed in the second study among infants fed Formula 305 these differences did not reach statistical significance

Of some interest is the lesser intake of bei kost in the second than in the first study Aver age intakes by male infants fed Formula 305 and Similac in the first study averaged 304 and 248 g/day respectively Corresponding in takes in the second study were 214 and 197 g/ day The explanation of this difference is un certain but it may be attributable at least in part to general changes in attitudes in the community toward early introduction and ex tensive feeding of beikost

Gain in weight and length

Gain in weight was significantly less ($p<0\ 01$) by male and female infants fed Formula 305 than by those fed Similac (Table 2) During the interval 112 through 167 days of age gain in weight by infants fed Formula 305 averaged for males 13 4 g/day in the first study and 11 4 g/day in the second study gain in weight by females (second study) averaged 11 3 g/ day Corresponding values for infants fed Similac were 18 1 19 3 and 16 1 g/day

Gain in weight per unit of energy intake (Table 2) was less by infants fed Formula 305 than by those fed Similac but the difference was significant ($p<0\ 02$) only in male infants in the second study A significant feeding related difference in gain in length was not demonstrated

Skinfold thickness

As previously mentioned skinfold thickness was measured only in the second study At the time of enrollment in the study (age 112 days)

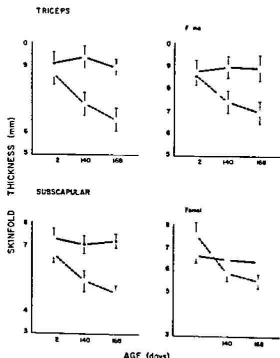

Fig 1 Triceps and subscapular skinfold thicknesses at various ages in relation to feeding by infants fed Similac (solid line) or Formula 305 (interrupted line) Formula 305 was a slightly modified skim milk with low caloric density At each age the mean and plus or minus one standard error of the mean are indicated

mean triceps skinfold thickness of males who were to be fed Formula 305 was 8 61 mm and that of males to be fed Similac was 9 08 mm This difference is not statistically significant ($p>0\ 05$) Corresponding values for mean sub scapular skinfold thickness of males were 6 61 and 7 29 mm The difference is not statistically significant Similarly for females there was no statistically significant difference in mean tri ceps or subscapular skinfold thickness be tween the two groups at the time of enroll ment Data on skinfold thickness of individual infants at various ages are presented in Appen dix II

As may be seen from Fig 1 little change in skinfold thickness of infants fed Similac oc curred between 112 and 168 days of age By contrast among male infants fed Formula 305 mean triceps skinfold thickness decreased 2 05 mm (an amount equal to 24% of the initial value) and mean subscapular skinfold thick

ness decreased 1 78 mm (27%) Corresponding decreases for female infants were 1 63 mm (19%) and 2 05 mm (27%) The differences between the initial and final skinfold thicknesses for infants fed Formula 305 were significant ($p<0$ 01) for each sex

DISCUSSION

We have previously studied the influence of caloric concentration of the formula on energy intake and growth of normal fullterm infants fed ad libitum from 8 to 112 days of age (3) Between 8 and 42 days of age caloric intake and gain in weight were less by infants fed a calorically dilute formula (50 kcal/100 ml) than by those previously observed (7) who had been fed formulas of conventional caloric concentration (67 kcal/100 ml) After 42 days of age energy intake and gain in weight were nearly identical for infants fed formulas of either concentration

In the present study caloric concentration of Formula 305 was 36 kcal/100 ml and average caloric concentration of the entire diet of these infants (Formula 305 plus beikost) averaged 44 kcal/100 ml The infants did not achieve energy intakes nor rates of gain in weight equal to those of infants fed a commercially prepared formula (average caloric density of diet of Similac plus beikost was 67 kcal/100 ml) As we shall discuss the chemical composition of weight gained by infants fed Formula 305 was probably abnormal

Data presented here provide the basis for calculations of a speculative nature that may offer further insights into the relation between calorie intake and the composition of growth during infancy Various assumptions must be made to permit these calculations We believe that the insights provided by this speculative approach may be valuable although the exact numbers employed in the calculations will almost certainly be imprecise

The following assumptions have been made (*a*) chemical composition of normal growth of male infants in the interval 112 through 167 days of age is the same as that described for the male reference infant (2*c*) between 4 and 12 months of age (*b*) male infants fed Similac in the present study demonstrated normal growth, (*c*) the energy cost of deposition of fat and protein from 4 to 12 months of age was identical to that presumed to apply to such deposition between birth and 4 months of age

The estimated energy cost of tissue synthesis is based on studies of growing animals (8) which suggest that deposition of 1 g of protein requires 7 5 kcal and that deposition of 1 g of fat requires 11 6 kcal We presume that other energy requirements for growth are relatively small compared with those for synthesis of protein and fat and that such additional energy requirements were inadvertently by the nature of the experiment included in the estimates of energy required for synthesis of protein and fat Although we consider these values the best available they may not be applicable to the human subjects considered here Nevertheless if one selects other values within the most probable range (e g the limiting values of 4 kcal/g of protein and 9 kcal/g of fat or the values apparently applicable for older animals (9) 15 96 kcal/g protein and 12 96 kcal/g fat) conclusions based on the calculations to be presented here will be altered relatively little

Because each 100 g of gain in weight between 4 and 12 months of age is assumed to include 21 0 g of protein and 19 1 g of fat (2*c*) the assumed energy cost of gain of 100 g of body tissue is 379 kcal or 3 79 kcal/g

As noted in Table 2 the average gain in weight by male infants fed Similac from 112 through 167 days of age in the first study was 18 1 g/day The energy cost of growth may therefore be estimated to be 69 kcal/day (18 1 g/day×3 79 kcal/g) Because total energy intake averaged 718 kcal/day it appears that 649 kcal/day were utilized for purposes other than growth (non growth) Assuming that the infants fed Formula 305 in the first study also required 649 kcal/day for non growth one might anticipate that with total energy intake

of only 575 kcal/day no growth would occur Yet gain in weight averaged 13 4 g/day

One likely explanation for this gain in spite of relatively low energy intake is that the infants fed Formula 305 were mobilizing energy from body stores of fat to permit growth of fat free tissue Assuming that protein accounts for 26 0% of fat free body mass synthesized between 4 and 12 months of age (2c) and that energy costs of synthesis of fat free body mass may be estimated from energy costs of synthesis of protein (i e other energy costs of synthesis of fat free body mass are included in the estimated cost of synthesis of protein) energy cost of synthesis of 100 g of fat free body mass may be estimated to be 195 kcal[1] (1 95 kcal/g) Thus mobilization of 1 g of fat providing 9 kcal would permit synthesis of 4 6 g of fat free tissue with a net gain of 3 6 g in body weight

If the hypothesis of mobilization of fat to permit synthesis of fat free tissue were correct we believed that skinfold measurements would reflect a sharp decrease in skinfold thickness of infants fed Formula 305 It was for this reason that the second study was carried out and in fact as may be seen from Fig 1 a dramatic decrease in skinfold thickness was recorded

As already mentioned the mean decrease in skinfold thickness of male infants fed Formula 305 between 112 and 168 days of age averaged 2 05 mm for triceps and 1 78 mm for the subscapular site These changes amounted to 24% and 27% respectively of the mean skinfold thickness recorded at 112 days of age Because it is likely that there was a greater decrease in the fat than in the non fat components of the skinfolds of infants fed Formula 305 a decrease of 24 to 27% in skinfold thickness suggests an even greater decrease in subcutaneous fat content at these sites

We have attempted to estimate the percentage of fat lost from the body by male infants fed Formula 305 in the second study through calculations unrelated to skinfold thickness For this approach it has been assumed that energy expenditures for nongrowth were similar for the two feeding groups The mobilization of 9 g of fat daily by the infants fed Formula 305 would provide 81 kcal/day Thus available energy would be 646 kcal/day (i e energy intake of 565 kcal/day for males in the second study plus 81 kcal/day from fat stores) Synthesis of fat free tissue of 20 4 g/day would be required the observed gain in weight of 11 4 g/day plus 9 0 g/day to replace the loss in weight from mobilization of fat Synthesis of fat free tissue would require 40 kcal (20 4 g ×1 95 kcal/g=40 kcal) and therefore 606 kcal/day (646 kcal−40 kcal=606 kcal) would be available for non growth—a value similar to that calculated for non growth (608 kcal/day[2]) for males fed Similac in the second study

The loss of 504 g of fat (9 g/day for 56 days) amounts to approximately 28% of the estimated 1 820 g present in the male reference infant at age 4 months (2c) Therefore one may speculate that approximately 28% of body fat content may have been lost in the 56 days of study

It is of course possible that energy expenditures for non growth may have been less for infants fed Formula 305 than for those fed Similac The study reported here does not provide clues about relative expenditures of energy for non growth in the two feeding groups

Although there can be little question that infants fed Formula 305 lost body fat the calculations are probably not quantitatively correct Even if they were however it would be difficult to estimate how long it would take for body stores of fat to become depleted The rate of depletion would be likely to decrease with increasing age because a larger percentage of calories would be derived from beikost as the infant got older Nevertheless in some

[2] 681 kcal−19 3 g×3 79 kcal/g=608 kcal

infants eventual depletion of fat stores might occur, thereby placing the infant in considerable jeopardy with respect to his ability to withstand a prolonged serious illness An additional cause for concern is the possibility that consumption of extremely large volumes of food in the apparent attempt to achieve adequate intakes of energy might establish undesirable habits of eating If excessive gastric filling were to become recognized by the infant as the signal to discontinue eating the infant might become quite slim while skim milk remained a major dietary component Later on however with access to foods of greater caloric density eating to the point of achieving similar gastric filling might lead to obesity

infants, eventual depletion of fat stores might occur thereby placing the infant in considerable jeopardy with respect to his ability to withstand a prolonged serious illness An additional cause for concern is the possibility that consumption of extremely large volumes of food in the apparent attempt to achieve adequate intakes of energy might establish undesirable habits of eating If excessive gastric filling were to become recognized by the infant as the signal to discontinue eating the infant might become quite slim while skim milk remained a major dietary component Later on however with access to foods of greater caloric density eating to the point of achieving similar gastric filling might lead to obesity

CLINICAL AND IMMUNOLOGICAL ASPECTS OF FOOD ALLERGY IN CHILDHOOD

I *Estimation of IgG IgA and IgE Antibodies to Food Antigens in Children with Food Allergy and Atopic Dermatitis*

A DANNAEUS S G O JOHANSSON T FOUCARD and S ÖHMAN

From the Department of Paediatrics the Blood Center and the Department of Dermatology University Hospital Uppsala Sweden

ABSTRACT Dannaeus A Johansson S G O Foucard T and Ohman S (Department of Paediatrics the Blood Center and Department of Dermatology University Hospital Uppsala Sweden) Clinical and immunological aspects of food allergy in childhood Acta Paediatr Scand 66 31 1977.—Sixtynine children with case histories of food intolerance and 30 food tolerant children with atopic dermatitis have been investigated regarding serum IgE levels and IgE- IgG and IgA-antibodies to some common foods Children with food intolerance had significantly higher IgE levels and to a larger extent specific IgE antibodies to the tested allergens IgE antibodies to cow s milk were found in 71% of the children with histories of cow s milk allergy but occurred also in similar titers in 27% of milk tolerant children with other food allergies IgE antibodies to egg white occurred in 88% of egg allergies but low and moderate titers were also found in 17% of children without food intolerance However all children with high titers had symptoms of egg allergy IgE antibodies to the fish allergen were only found in fish allergic children while IgE antibodies to soy bean and green peas were found less consistently The level of serum IgA antibodies to milk was similar in both groups The IgG antibody titers to all tested food antigens seemed to parallel the IgE antibody titer to the same food It was not possible to correlate the IgG antibody titers to symptoms

KEY WORDS Food allergy atopic dermatitis

In children adverse reactions to ingested foods can be caused by a reaction between an ingested food allergen and its corresponding IgE antibody Therefore the quantification of serum IgE and IgE antibody to food allergens may be an important tool in the investigation of patients with food intolerance (8)

This study was done as an attempt to shed further light on the participation of IgE antibodies in relation to antibodies of other classes of immunoglobulins in children with symptoms suggestive of food intolerance History and symptoms were correlated to the serum IgE level and to the levels of IgE IgG and IgA antibodies to some common food allergens

MATERIALS

The clinical material consisted of 99 children 48 boys and 51 girls ranging in age from 3 months to 15 years

The patients were investigated at the University Hospital outpatient clinics and divided into two groups The criterion for admission to Group I was a clinical history of food intolerance based on the parents observations Specific foods were suspected as causative when the reactions were clearly related to food ingestion and when striking improvement followed food elimination Reported manifestations included eruption of eczema urticaria angiooedema circumoral rash or gastrointestinal symptoms such as vomiting diarrhoea and sometimes abdominal pains Asthma and anaphylactic shock had occurred in some patients Sixty three of the children in Group I had eczema varying from very slight to severe and in addition 21 had asthma and/or allergic rhinitis

Group II consisted of 30 children with atopic dermatitis without any obvious intolerance to foods In this group only one patient had asthma and four children had hay

Table 1 *Some of the most common food allergens suspected by the parents of 69 children with a history of food intolerance (Group I)*

Suspected food	No of subjects	%
Egg	35	51
Fish	23	33
Citrus	22	32
Chocolate	20	29
Tomatoe	18	26
Nuts	15	22
Cow s milk	7	10
Green peas	3	4
Soy bean	0	0

fever A standard questionnaire was used to obtain a history of the patients and their families All except four were seen by one of us (A D) In addition to a detailed history and physical examination venous blood samples were drawn from each patient After clotting sera were sparated and stored at −20°C until analyzed

The age distribution was similar in both groups as was the age at onset of eczema A family history of eczema asthma and allergic rhinitis was obtained with about the same frequency in Group I and II but the relatives of the children in Group II generally had more vague symptoms

The children of Group I often had multiple food hyper sensitivities (Table 1) It is to be noted that 50% of them reported intolerance even to foods not listed in the table but only single patients reacted to each of these foods

METHODS

The IgE concentrations were measured by a direct sand wich type of radio-immuno-sorbent technique PRIST (Ceska & Lundkvist 1972) (4)

IgE antibody activity was determined by the radio-allergosorbent test RAST (19) as described in detail (10) The results of RAST were expressed as parts per thou sand (‰) of a reference serum with 1‰ or more considered positive All tests were done in duplicate

IgG and IgA antibody activity was measured by a modified RAST technique using radiolabeled immunosorbent purified rabbit anti IgG and IgA The cpm activity on the disc was after subtraction of the cpm of a negative serum pool expressed in parts per thousand (‰) of a cow s milk reaginic serum An activity exceeding 5 of that in the reference serum was considered positive IgG anti bodies to a purified fish allergen DS22 were measured by a method based on the binding of IgG antibody to Sepharose coated staphylococcus protein A (11) as described in detail (6) One tenth ml of a serum sample diluted 1/10 was incubated with 0 5 ml Sepharose protein A (Seph pA) for 2 hours The ^{125}I labeled DS22 allergen representing approx 100 000 cpm was then added for a second incubation over night After washing the radio-activity bound to Seph pA was measured in a gamma counter and expressed in parts per thousand of a reference serum

Allergens used in the experiments

The allergen were coupled to the cyanogen bromide activated cellulose paper discs as described (10) The non specific binding of IgE was tested against a non reaginic serum having an IgE level of approx 5 000 U/ml and for all allergen found to be 1‰

For the preparation of 1 000 allergen coated discs the following allergen preparations were used respectively

1ml of commercial fresh evaporized skimmed (lipid concentration 0 05%) cow s milk

29 mg of an egg white extract ($E280^{1cm}_{1\%} = 14$) as described by Bleumink & Young (3)

5 ml of crude fish extract (Vitrum AB Stockholm) batch nr 8152 1/10 w/v

A soy bean extract from a commercial soy protein (soja protein HKC) with 90% soy protein according to the specification prepared by dissolving 3 g in 30 ml 0 15 M saline After centrifugation 2 ml of the supernatant was used

A green pea extract prepared by extraction of 700 g grounded commercial deep frozen green peas (Felix AB Sweden) in 250 ml distilled water The mixture was centrifuged and 0 4 ml of the supernatant was used

20 μg of a purified cod fish muscle allergen DS 22 (1) kindly provided by Dr K Aas Oslo and Dr H Bennich Biomedical Centre Uppsala was labeled with 2 mCi ^{125}I using the Chloramine T technique (9)

Skin prick tests were performed with the same extracts *A wheal size of 2 mm* or more greater than the control was considered positive

RESULTS

The serum IgE level varied from 15 to 3 000 U/ml (arithmetic mean 455 U/ml) in Group I and from 15 to 350 U/ml (arithmetic mean 104 U/ml) in Group II The highest IgE levels were found in children who had coexistent asthma and allergic rhinitis (Fig 1) The average number of positive RAST tests was highest in Group I but increased in both groups with the IgE level

Cow s milk allergy

Seven children in Group I had a case history suggesting cow s milk allergy (Table 2) After milk ingestion five of them (numbers 2 3 4 6 7) were reported to have vomiting and diarrhoea and one of them also urticaria (number 1) Four of them (numbers 2 3 4 5) had eruption of the eczema when milk was ingested

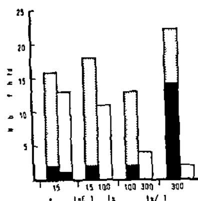

Fig 1 The distribution of serum IgE levels in 69 children with a history of food intolerance (Group I hatched bars) and in 30 eczema patients without symptoms indicative of food intolerance (Group II open bars) The number of patients with inhalant allergy is indicated by filled areas

Table 2 *The IgE levels and cow s milk antibody concentrations in serum of seven children with histories suggestive of cow s milk allergy*

The antibody values are expressed in parts per thousand of a standard

Case no	Age (mo)	IgE (units/ ml)	IgE antibodies (‰)	IgG anti bodies (%)	IgA antibodies (%)
1	16	157	9	970	195
2	20	3 000	2 570	182	1 000
3	9	48	5	230	340
4	58	193	3	200	1 000
5	3	26	7	40	240
6	10	10	<1	80	185
7	9	10	<1	87	290

The reactions were of the immediate type in all but 2 children (numbers 6 and 7) who had symptoms of delayed onset Five of the children had IgE antibodies to milk and raised serum IgE levels for their age Two patients (number 6 and 7 had normal serum IgE levels and no detectable IgE antibodies to milk All seven patients had antibodies to milk of the G and A immunoglobulin classes The highest levels were found in patients who also had IgE antibodies to milk (Table 2) IgE antibodies to milk could also be detected in children without obvious symptoms of cow s milk allergy (Table 3) Such antibodies were more frequent in Group I than in Group II No consistent covariation was found between the titers of IgE IgG and IgA antibodies Nor was there found any relationship between the antibody titers and clinical symptoms

Egg allergy

35/69 children (51 %) in Group I had histories suggesting egg allergy (Table 4) The symptoms varied from anaphylactic shock to a slight circumoral rash according to the parents observations 88 % of the egg hypersensitive children had detectable IgE antibodies to raw egg white and the titers seemed well correlated to the degree of clinical hypersensitivity All children with a titer exceeding 10‰ had symptoms of egg allergy

Four patients with a history of egg allergy had negative RAST tests A skin prick test with raw egg white was negative in these four children When challenged orally two children

Table 3 *Frequency of IgE IgG and IgA antibodies to cow s milk in children without obvious intolerance to milk in Groups I and II*

Antibody type	Group I %	Group I Mean titer ( )	Group I Range (‰)	Group II %	Group II Mean titer (‰)	Group II Range ( )
IgE	7	10	<1– 85	3	?	–
IgG	89	95	<1– 970	100	136	17– 450
IgA	100	380	5 –1 000	100	405	16–1 000

Table 4 *Frequency of IgE antibodies (positive RAST tests) and IgG antibodies to raw egg white*

35 children hypersensitive to egg (Group I) and 30 children without food intolerance (Group II)

	Group I			Group II		
Antibody type	%	Mean titer (‰)	Range (‰)	%	Mean titer (‰)	Range (‰)
IgE	88	275	<1-1 000	17	1 8	<1-2 0
IgG	94	98	<1- 600	67	38	<1-260

had circumoral rashes and two had no reaction

Low titers of IgE antibodies to raw egg white were also found in 21% of the children not sensitive to egg but to other foods These children also had positive skin tests with the egg white allergen

In Group II there were five patients (17%) who had IgE antibodies to raw egg white at even lower levels (Table 5) Only one of them had a positive skin prick test All but two of the egg allergic children had detectable amounts of IgG antibodies to egg white These two children had negative RAST tests The mean IgG antibody titer in Group I was significantly higher than in Group II $p<0\ 05$ (Table 4) The levels roughly parallelled the IgE antibody level but there were exceptions Five patients with very high IgE antibody titers to raw egg white had rather low titers of IgG antibodies The clinical symptoms of these children were not different from others

Fish allergy

24 children gave a history of fish allergy All types of reactions were represented but anaphylactic reactions in the respiratory and gastro intestinal tract dominated Quincke oedema urticaria and feeling of swelling and itching in the throat were also common symptoms

IgE antibodies were found in 16 children (67%) and only when the history indicated fish intolerance (Table 5)

All patients with a positive fish RAST had high serum IgE levels and symptoms of asthma or wheezy bronchitis Fish was generally not the only offending food All 16 children also had a varying degree of clinical egg hyper sensitivity and positive RAST to raw egg white Several patients also had intolerance to other foods

In children with a history of fish hypersensitivity IgG antibodies to fish as measured by RAST were demonstrable twice as often as in

Table 5 *Frequency of IgE antibodies (positive RAST tests) and IgG antibodies to isolated fish allergen DS 22*

Serum from 24 children with fish allergy according to history (Group I) and from 30 children without food intolerance (Group II)

	Group I			Group II		
Antibody	%	Mean titer (‰)	Range (‰)	%	Mean titer ( )	Range (‰)
IgE	67	395	<1-4 633	0	0	0
IgG	46	16	<1- 47	23	14	<1-155
IgG to DS 22	67	360	<1-2 315	0	0	0

Table 6 *Frequency of IgE antibodies (positive RAST tests) to soy bean and green peas and of IgG antibodies to soy bean*

Antibody type	Allergen	Group I %	Group I Mean titer (%)	Group I Range (%)	Group II %	Group II Mean titer (%)	Group II Range (%)
IgE	Soy bean	46	130	<1–1 683	23	3 8	<1–15
	Green peas	23	22	<1– 170	3	2 4	–
IgG	*Soy bean*	*58*	14	<1– 180	47	5	<1–2?

children with other kinds of food intolerance or in the children of Group II (Table 5) IgG antibodies to the pure fish allergen DS 22 as measured by the protein A technique showed a higher correlation to fish allergy and in Group I only those patients who had IgE anti bodies to fish had IgG antibodies to DS 22 The individual IgG antibody titer also roughly parallelled the titer of IgE antibody Fish sen sitive children with a negative RAST had more vague and less dramatic symptoms than the RAST positive children They also had normal serum IgE values and they neither had IgG antibodies to crude fish extract nor to DS 22 None of them had asthma or wheezy bron chitis

Soy bean and pea allergy

Although none of the children in this study was reported to be intolerant to soy bean 35 children were RAST positive against the soy bean allergen (Table 6) Skin prick tests per formed in 14 of those children were only posi tive in five cases who all had a RAST titer exceeding 15 %

IgG antibodies to soy bean were also a fre quent finding The highest titers (*mean 17%*) *and highest frequency of positive tests (70%)* were found in patients who had IgE antibodies to soy bean and the lowest titers were found in the children of Group II (Table 6)

Only three children gave a history sugges tive of pea allergy and they were all RAST positive to the pea allergen preparation with a mean titer of 29% However a further four teen children had demonstrable IgE antibodies of similar titers to the pea extract All children with IgE antibodies to the pea allergen also had a positive RAST test *to the soy bean prep*aration It was also found that fourteen out of 22 (67%) children positive in RAST to cow s *milk were positive in RAST to the* soy bean allergen

DISCUSSION

Most positive RAST tests were found in chil dren with high serum IgE levels

However in the youngest children with food intolerance it was often possible to find IgE antibodies to the tested foods even when the serum IgE was only *slightly elevated in* relation to age

Children with respiratory allergy in addition to eczema had *in agreement with* earlier re ports (20) high serum IgE levels including high RAST titers to the tested foods In these patients it was obvious that the titers did not always reflect the degree of clinical food hypersensitivity

Some patients reporting multiple food hy persensitivities had normal serum IgE concen trations and no detectable amount of IgE anti bodies *to the tested foods* Their *symptoms* were probably based on other immunological or non immunological mechanisms (2 14 16)

It is evident from this study and others (5) that IgE antibodies to cow s milk occur in

Table 4 *Frequency of IgE antibodies (positive RAST tests) and IgG antibodies to raw egg white*

35 children hypersensitive to egg (Group I) and 30 children without food intolerance (Group II)

	Group I			Group II		
Antibody type	%	Mean titer (%)	Range (%)	%	Mean titer (%)	Range (%)
IgE	88	275	<1-1 000	17	1 8	<1-2 0
IgG	94	98	<1- 600	67	38	<1-260

had circumoral rashes and two had no reaction

Low titers of IgE antibodies to raw egg white were also found in 21% of the children not sensitive to egg but to other foods These children also had positive skin tests with the egg white allergen

In Group II there were five patients (17%) who had IgE antibodies to raw egg white at even lower levels (Table 5) Only one of them had a positive skin prick test All but two of the egg allergic children had detectable amounts of IgG antibodies to egg white These two children had negative RAST tests The mean IgG antibody titer in Group I was significantly higher than in Group II $p<0.05$ (Table 4) The levels roughly parallelled the IgE antibody level but there were exceptions Five patients with very high IgE antibody titers to raw egg white had rather low titers of IgG antibodies The clinical symptoms of these children were not different from others

Fish allergy

24 children gave a history of fish allergy All types of reactions were represented but anaphylactic reactions in the respiratory and gastro-intestinal tract dominated Quincke oedema urticaria and feeling of swelling and itching in the throat were also common symptoms

IgE antibodies were found in 16 children (67%) and only when the history indicated fish intolerance (Table 5)

All patients with a positive fish RAST had high serum IgE levels and symptoms of asthma or wheezy bronchitis Fish was generally not the only offending food All 16 children also had a varying degree of clinical egg hypersensitivity and positive RAST to raw egg white *Several patients also had intolerance to* other foods

In children with a history of fish hypersensitivity IgG antibodies to fish as measured by RAST were demonstrable twice as often as in

Table 5 *Frequency of IgE antibodies (positive RAST tests) and IgG antibodies to isolated fish allergen DS 22*

Serum from 24 children with fish allergy according to history (Group I) and from 30 children without food intolerance (Group II)

	Group I			Group II		
Antibody	%	Mean titer (%)	Range (%)	%	Mean titer (%)	Range (%)
IgE	67	395	<1-4 633	0	0	0
IgG	46	16	<1- 47	23	14	<1-155
IgG to DS 22	67	360	<1-2 315	0	0	0

low RAST titers to specific allergens seem to be significant in children with clear cut symptoms of food allergy However later in child hood low levels of IgE antibodies to milk and egg seem to occur frequently even in children without obvious food intolerance (5) Whether this tolerance is caused by a diminished re sorption of allergen the occurrence of anti bodies with blocking capacity decreased sen sitivity for biological mediators in the target organs or some other mechanisms remains to be ascertained

rather high frequency even in children without obvious allergy to milk It is remarkable that in our study, only one of the milk intolerant children had a higher IgE antibody titer to milk than 16 milk tolerant children who had positive RAST tests to milk The clinical significance of a positive milk RAST seems to be highest in children 0–2 years of age

It seems reasonable that milk allergy in some patients can be triggered by an IgE antibody reaction especially when milk ingestion gives immediate symptoms from the skin and from the gastro intestinal tract The bad correlation between symptoms and IgE antibody titers is surprising Possible explanations are that the IgE milk antibody titer in serum does not reflect the true concentration of IgE antibodies in the mucous membranes and in the skin In addition to the allergen IgE antibody reaction several other factors may contribute to the symptomatology of cow s milk allergy

The presence of IgG antibodies to cow s milk is probably a physiological phenomenon in childhood (13) The titers often parallelled the IgE antibody titer to milk Even children on a milk free diet had in some cases high titers

IgA antibodies to cow s milk are also reported to be frequent in early childhood (13) In our study they seemed to occur parallel with the IgE antibodies It has been suggested that the maturation of the IgA system influences the liability of the child to produce IgE antibodies to food allergens (18) In our study the IgA antibody titer to milk could not be correlated either to IgE antibody titers to milk or to clinical symptoms

The clinical significance of both positive skin tests and RAST in egg white allergy is disputed (17) We found a good correlation between RAST titers and clinical symptoms No patient had a titer exceeding 10‰ without clinical symptoms of egg allergy Patients with low titers must be judged individually but generally no clinical hypersensitivity could be shown

IgG antibodies to egg-white were common in all children and parallelled the IgE antibody titer with few exceptions Many children showed increasing tolerance to egg and in these cases a high IgG antibody titer was a frequent finding Whether this high IgG antibody titer with a possible blocking capacity contributes to the increased tolerance to egg or is just a result of an increased allergenic load is not known

Fish allergy often gives systemic reactions and fish allergic children seemed to be less liable to outgrow their allergy during childhood In our study IgE antibodies to fish allergen were only demonstrated in the fish hypersensitive children and the titers were correlated to the degree of clinical sensitivity A rather high frequency of IgG antibodies to the crude fish allergen was found in children who were not sensitive to fish On the other hand only fish allergic children had IgG antibodies to the purified cod muscle allergen DS 22 This illustrates the need for purified allergens in the study of antibody patterns in atopic allergy

This study confirms reports that soy bean is a more potent immunogen than earlier believed (7) It is also worth noting that IgE antibodies to soy bean are a common finding in children with IgE antibodies to milk Several children had antibodies to both soy bean and green peas Whether this is caused by a higher immunoreactivity in these children or some cross reactivity on the basis of structural similarities between these allergens is not evident but the latter view is supported by a report that the legume family has allergenic determinants in common (15) Green peas were rarely suspected as an allergen and the significance of the high frequency of positive RAST tests to this allergen was difficult to evaluate

Food intolerance may be based on a multitude of different mechanisms Nevertheless the determination of the serum IgE level and IgE antibodies to certain food allergens can be helpful in evaluating the importance of type I reaginic allergy in individual cases In the first year of life even slightly raised IgE values indicate an atopic disposition (12) and even very

low RAST titers to specific allergens seem to be significant in children with clear-cut symptoms of food allergy However later in childhood low levels of IgE antibodies to milk and egg seem to occur frequently even in children without obvious food intolerance (5) Whether this tolerance is caused by a diminished resorption of allergen the occurrence of antibodies with blocking capacity decreased sensitivity for biological mediators in the target organs or some other mechanisms remains to be ascertained

HIGH DENSITY LIPOPROTEIN CONCENTRATIONS IN NEWBORN INFANTS

B E GINSBURG and R ZETTERSTRÖM

From the Department of Paediatrics Karolinska Institute St Goran s Children s Hospital Stockholm Sweden

ABSTRACT Ginsburg B E and Zetterstrom R (Department of Paediatrics Karolinska Institute St Goran s Children s Hospital Stockholm Sweden) High density lipoprotein concentrations in newborn infants Acta Paediatr Scand 66 39 1977.—The lipoprotein pattern was analyzed by agarose gel electrophoresis in 19 newborn infants of varying gestational age The HDL concentration was determined by rocket immunoelectrophoresis in another 41 newborn infants Infants with a gestational age of <33 weeks had very low HDL concentrations compared to preterm infants with a gestational age of ≥33 weeks and term infants In the first 5–10 days after birth the HDL concentration increased markedly in preterm infants (gestational age <37 weeks) whereas it remained unchanged in term infants

KEY WORDS Newborn preterm lipoprotein pattern alfa lipoprotein HDL

Although HDL constitutes more than 50% of the total lipoproteins in the newborn infant this fraction has received very little attention In a study of the lipoprotein pattern in new born infants we observed that the alfa lipoprotein fraction (HDL) represented only about 10–15% of the total lipoproteins in newborn infants with a gestational age (gest age) below 33 weeks The concentration of HDL in serum obtained from newborn infants of varying gest age was determined and compared to the post natal age

MATERIALS AND METHODS

Materials

All infants were appropriate for gest age as judged by weight and length The lipoprotein pattern was analyzed on EDTA-plasma obtained from 11 term and 8 preterm infants The HDL concentration was determined on serum samples obtained from 39 term and 1? preterm infants In the preterm infants feeding was started within four hours after delivery by giving human breast milk in rapidly increasing amounts as devised by Davies (12) In infants with a gest age >36 weeks feeding was started 6–8 hours after delivery by giving 10 ml 5 5% glucose and after an additional 3–4 hours they were nursed by their mothers

Methods

Lipoprotein electrophoresis Lipoprotein agarose gel electrophoresis was carried out according to the method described by Noble (11) The electrophoretogram was evaluated by densitometric scanning (5)

HDL was determined by rocket immunoelectrophoresis (10) The antiserum used was rabbit anti human HDL kindly supplied by Bengt Johansson Lund Since no international standard is available the samples were related to an adult pooled blood donors standard

Statistical methods

The relation of HDL concentration to gest age was assessed with Sperman rang correlation test (3) and comparison of HDL levels in infants with a gest age of <33 weeks and ≥33 weeks respectivley was assessed with Student s *t* test

---

Abbreviations HDL=high density lipoprotein S E = standard error S D =standard deviation

Comparison of the postnatal increase in HDL concentration in preterm and term infants was assessed with the Wilcoxon sum of ranks test (4)

RESULTS

Lipoprotein pattern In term newborn infants alfa lipoprotein prebeta and beta lipoprotein accounted for 50 0±3 2% S E 11 0±1 8% and 37 3±2 5% of the total lipoproteins respectively In five term infants there was no difference between the lipoprotein pattern in cord blood and in blood collected from a peripheral vein nor did the pattern change within the first 9 hours Infants with a gest age of <33 weeks had very low alfa lipoprotein levels (13 9±3 5% S E) (Fig 1)

HDL concentration The HDL concentration in term newborn infants was 73 6±3 9% S E of the adult standard No difference was found between the HDL concentration in cord blood and in blood collected from a peripheral vein within 34 hours after delivery Infants with a gest age <33 weeks had lower HDL concentrations than infants with a gest age ≥33 weeks (p<0 01) (Fig 2) Whether there is a rather rapid rise in the 32nd–34th week of gestation or a continuous rise during a longer period can not be concluded from this study because of the small material During the first 5–10 days after delivery the HDL concentration rose markedly in preterm infants (gest age <37 weeks) but no consistent change was noted in term infants The difference was statistically significant (p<0 01) (Fig 3) After the initial rise no changes were noted during the following 3–5 weeks

DISCUSSION

There are many methodologic problems involved in performing lipoprotein electrophoresis during the neonatal period The colour density of the alfa region is increased by lipids and bilirubin bound to albumin The high levels of nonesterified fatty acids and bilirubin in the plasma of newborn infants reduce the reliability of the densitometric scan Immunologic quantitation of HDL is also associated with difficulties since HDL consists of several polypeptides These errors have to be taken into account in the evaluation of the results

This study confirms earlier observations in term newborn infants that alfa lipoprotein levels represent about 50% or more of the total lipoproteins (1 6 13) The HDL concentration in term newborn infants was found to be 73 6±3 9% of the adult value (S E) which is in good agreement with the value of 74 4± *15 1% (S D) reported by Davidsen (2)* In preterm infants with a gest age of <33 weeks

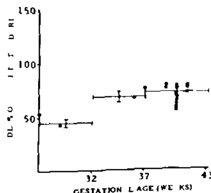

Fig 2 Serum HDL concentrations in relation to gest age The vertical bars indicate the standard error (S E) in three groups with gest age <33 33–37 and >37 weeks respectively

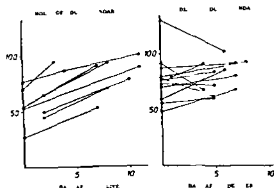

Fig 3 Changes in the serum HDL concentration after delivery in preterm (left) and term infants (right)

the HDL concentration was very low (45 1± 4 2%) Davidsen (2) also found low HDL values in infants with a gest age of <31 weeks (56 8% of adult values) the HDL values were highest in infants with a gest age of 35–38 weeks (84 0%) although they did not differ significantly from the values in infants with a gest age of 31–34 weeks and 39–42 weeks (78 6% and 74 4% respectively) In the study presented here the HDL concentration seemed to increase until the 33rd week of gestation but showed no further increase up to term It is tempting to speculate that the increase in the concentration of HDL which transports the majority of the serum phospholipids is related to a start of the biosynthesis of various phospholipids such as synthesis of surfactant factors (7 9) The major apo-HDL polypeptide apo-AI (apo-LP threonine) which represents 65–75% of the total HDL apoproteins is a co-factor to lecithin-chol esteryl acyl transferase (LCAT) (8)

Whether a low apo-AI concentration is the main cause for the low HDL level seen in infants with a gest age <33 weeks remains to be determined

The postnatal rise in HDL found in preterm infants markedly exceeded the prenatal alterations

ACKNOWLEDGEMENT

We wish to express our sincere gratitude to Dr Bengt Johansson Department of Clinical Chemistry Lund Hospital for valuable advice and for supplying the anti serum

CONCENTRATIONS OF TRIGLYCFRIDES FREE FATTY ACIDS AND GLYCEROL IN CORD BLOOD OF NEWBORN INFANTS WITH A BIRTH WEIGHT OF ≤2 700 GRAMS

NIELS CHRISTIAN CHRISTENSEN

From the Departments of Obstetrics and Paediatrics Odense University Hospital Odense Denmark

ABSTRACT Christensen N C (Departments of Obstetrics and Paediatrics Odense University Hospital Odense Denmark) Concentrations of triglycerides free fatty acids and glycerol in cord blood of newborn infants with a birth weight of ≤2 700 grams Acta Paediatr Scand 66 43 1977.—Concentrations of triglycerides free fatty acids (FFA) and glycerol were measured in umbilical venous blood from 99 infants with a birth weight of between 1 100–2 700 g and a gestational age of 27–41 weeks Thirty infants were small for gestational age (SGA) 58 were appropriate (AGA) and 11 were of uncertain gestational age In AGA infants with a gestational age of ≤35 weeks FFA values were lower than in those with a gestational age of >35 weeks otherwise concentrations of triglycerides FFA and glycerol were independent of birth weight and gestational age in AGA infants In SGA infants higher FFA values were found compared with both AGA and term infants of normal birth weight Triglyceride values were higher in SGA than in AGA infants In SGA infants a significant positive correlation was found between gestational age and concentrations of both FFA and triglycerides No differences in FFA glycerol and triglyceride concentrations were seen between asphyxiated and non asphyxiated AGA infants

KEY WORDS Cord serum newborn low birth weight FFA glycerol triglycerides

Interest in the determinations of lipids in the cord blood has increased in recent years mainly in order to obtain an early diagnosis in children suffering from primary hyperlipoproteinemia Thus it appears possible to find children with primary hypercholesterolemia by measuring the concentration of either cholesterol (14) or very low density lipoprotein cholesterol (8) in the cord blood

In order to define more clearly these conditions it is necessary to understand the factors apart from the genetical that can influence the lipoprotein concentrations in cord blood This does not appear to have been studied sufficiently with regard to the triglyceride concentrations as the relatively few investigations published so far have given conflicting results

Sabata et al (11) studied the influence of asphyxia on the triglyceride concentration in cord blood and found the same values in children with slight and severe asphyxia and in children from a control group On the other hand Tsang et al (13) and Andersen & Friis Hansen (1) found that hypertriglyceridemia occurred more frequently in children with asphyxia than in those who had not

The triglyceride concentrations in cord blood from infants with a low birth weight has been studied by Fosbrooke & Wharton (5) who found that infants with low birth weight born at term had higher triglyceride values than mature infants of normal weight who again had higher values than premature infants Neither Brody & Carlson (2) nor Sabata et al (12) were able to demonstrate any difference between premature and mature infants by measuring the triglyceride concentrations

The present investigation was carried out in

Table 1 *Concentrations of triglycerides FFA and glycerol in umbilical venous blood*

All infants without asphyxia grouped according to birth weight Mean values for term infants with birth weight >3 000 g are inserted

Birth weight (g)	n	Triglycerides (mmol/l)		FFA (mmol/l)		Glycerol (mmol/l)	
		Mean	S D	Mean	S D	Mean	S D
≤1 500	3	0 47	0 28	0 19	0 07	0 07	0 01
1 501–2 000	15	0 43	0 14	0 20	0 12	0 06	0 04
2 001–2 500	31	0 58	0 27	0 27	0 13	0 07	0 04
2 501–2 700	12	0 49	0 23	0 23	0 10	0 07	0 02
Normal newborn infants (3)		0 52		0 24		0 07	

Only the difference between triglyceride values for the weight groups 1 501–2 000 and 2 001–2 500 is significant ($p<0$ 05 t test)
$n=37$

order to determine the concentration of triglycerides in cord blood from infants of low birth weight but of different gestational ages and with various perinatal complications including asphyxia The results were compared with the findings in a previous study of normal newborn infants (3)

There is a close metabolic relationship between free fatty acids (FFA) and triglycerides and an increase in the triglyceride concentration may have been preceded by an increased mobilization of FFA from adipose tissue providing the possibility of increased hepatic synthesis of triglycerides Therefore concentrations of FFA and glycerol have also been measured

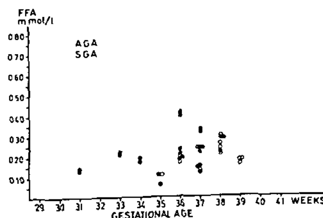

Fig 1 Relationship between cord blood FFA and gestational age

MATERIAL

The material includes 99 infants with a birth weight of ≤2 700 g and gestational ages of 27–41 completed weeks All children were born in the Department of Obstetrics Odense University Hospital The gestational age was calculated from menstrual data where these were reliable supplemented by clinical evaluation In 11 cases the gestational age could not be estimated with sufficient accuracy and these infants were excluded from the calculations as regards gestational age

Estimated on the basis of weight curves from this hospital (15) 30 infants were small for gestational age (≥2 S D below mean weight for gestational age) SGA infants while 58 were appropriate for gestational age AGA infants Mean weight and gestational age for SGA infants were 2 247 g and 38 2 weeks and for AGA infants 2 201 g and 35 0 weeks respectively The difference between the gestational ages was highly significant Twins and children born of mothers with chronic diseases such as diabetes mellitus were not included

Eighty seven of the women had uncomplicated pregnancies Among the others six had preeclampsia Thirteen of the infants were born by Caesarean section in 17 cases the birth was provoked using drugs and two infants were born by vacuum extraction

Asphyxia was evaluated from the Apgar score and arbitrarily divided into severe and slight asphyxia Slight asphyxia was defined by a 1 minute score of <7 and a 5 minute score ≥7 while severe asphyxia was present when both scores were <7 12 infants had slight and seven severe asphyxia

METHODS

Immediately following delivery blood was drawn from the umbilical vein Part of the sample was stabilized with EDTA Samples were centrifuged immediately or within 1 hour following storage at 4°C Analysis was performed on fresh centrifu[illegible]

Serum was analysed for triglycerides and glycerol (4) and plasma for FFA using the method of Laurell & Tibbling (9) as described previously (3)

RESULTS

The influence of birth weight gestational age and nutritional status on the concentrations of triglycerides glycerol and FFA was studied in 69 infants who did not suffer from asphyxia and showed no sign of disease during the first day of life 38 of the infants were AGA 24 were SGA and seven of uncertain gestational age

Table 1 shows triglyceride FFA and glycerol values for the infants grouped according to birth weight No differences between the various groups were found except for the significantly higher triglyceride values among infants with a birth weight of 2 001–2 500 g compared with those with a birth weight of 1 501–2 000 g Study of correlations between birth weight and concentrations of triglycerides glycerol and FFA respectively did not reveal any significant correlations in the whole group or when SGA and AGA infants were analysed separately

Relationships between gestational age and concentrations of FFA and triglycerides are shown in Figs 1 and 2 There was an increase in both the FFA and the triglyceride concentration after 35 weeks resulting in significant

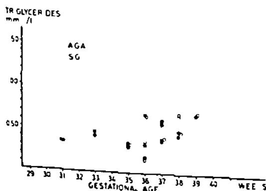

Fig Relationship between cord blood triglyceride values and gestational age

Table 2 *Coefficient of correlation (r) and levels of significance (p) between gestational age and concentrations of triglycerides and FFA in umbilical venous blood*

	r	*n*	*p*
All infants			
FFA versus gestational age	0 4410	62	<0 001
Triglycerides versus gestational age	0 39[illegible]	56	<0 01
AGA			
FFA versus gestational age	0 30[illegible]1	38	>0 05
Triglycerides versus gestational age	0 1697	36	>0 05
SGA			
FFA versus gestational age	0 4662	[illegible]4	<0 05
Triglycerides versus gestational age	0 5[illegible]8[illegible]	[illegible]0	<0 05

correlations between gestational age and concentrations of FFA and triglycerides (Table 2)

Inspection of the individual values in Figs 1 and 2 showed that the correlations between gestational age and FFA and triglyceride concentrations were caused mainly by the higher values in the SGA infants When SGA and AGA infants were analysed separately a significant correlation between gestational age and concentrations of triglycerides and FFA was found in the SGA infants only (Table 2) No significant correlation was found between gestational age and concentration of glycerol

As shown in Table 3 SGA infants had significantly higher triglyceride and FFA values than AGA infants whereas no difference was found in glycerol concentrations

Although there was no significant correlation between FFA concentration and gestational age it was found that AGA infants born before 36 weeks gestation had significantly lower FFA values than those born after 36 weeks gestation (Table 4) The mean values of triglycerides FFA and glycerol for AGA infants of more than 35 weeks gestation closely resemble those found in term infants of normal birth weight

Table 3 *Concentrations of triglycerides FFA and glycerol in umbilical venous blood from AGA and SGA infants*

	n	Triglycerides (mmol/l)		FFA (mmol/l)		Glycerol (mmol/l)	
		Mean	S D	Mean	S D	Mean	S D
AGA	36	0 47	0 19	0 21	0 08	0 07	0 04
SGA	20	0 61	0 29	0 30[b]	0 15	0 06	0 04
p values t test		<0 05		<0 01		>0 05	

n=38 [b] n=24

When SGA infants with a gestational age of 38–41 weeks were compared with term infants with a birth weight of >3 000 g (Table 1) significantly higher FFA values were found among the SGA infants (0 35 mmol/l versus 0 24 mmol/l t test p<0 01) The triglyceride values were also higher in SGA infants (0 68 mmol/l) but the difference was not significant as evaluated by the t test

A comparison of AGA and SGA infants of 35–38 weeks gestation did not reveal any significant differences between mean values of FFA triglyceride and glycerol concentrations although SGA infants had marginally higher FFA and triglyceride values (AGA/SGA infants FFA 25/29 mmol/l triglycerides 49/59 mmol/l)

An attempt to find a correlation between concentrations of triglycerides and FFA and the degree of intrauterine malnutrition (expressed as

$$\left(\frac{\text{birth weight} \times 100}{\text{mean birth weight for gestational age}}\right)$$

in SGA infants did not reveal any significant correlation

Eight babies with a mean birth weight of 2213 g and a mean gestational age of 37 3 weeks were delivered by Caesarean section and did not suffer from asphyxia Five of these were SGA Cord blood concentrations of triglycerides and FFA (0 54 mmol/l and 0 23 mmol/l) did not differ from the values obtained from infants born by spontaneous vaginal birth The concentration of glycerol was found to be lower for infants born by Caesarean section than for those born by vaginal birth (0 05 mmol/l versus 0 08 mmol/l p< 0 05)

Fourteen infants (10 AGA two SGA two of uncertain gestational age) with a mean birth weight of 2 314 g and a mean gestational age of 36 2 weeks were born by provoked labour using synticinon papaverin drop and with a normal Apgar score These infants had a mean triglyceride value that was slightly lower (0 42 mmol/l) than that found in infants born by spontaneous labour but the difference was not

Table 4 *Concentrations of triglycerides FFA and glycerol in umbilical venous blood from AGA infants grouped according to gestational age*

	n	Triglycerides(mmol/l)		FFA (mmol/l)		Glycerol (mmol/l)	
		Mean	S D	Mean	S D	Mean	S D
Gestational age ≤35 weeks	19	0 44	0 17	0 18	0 06	0 06	0 03
Gestational age >35 weeks	17	0 50	0 21	0 25	0 08	0 08	0 04
p values t test		>0 05		<0 01		>0 05	

significant nor did these infants differ from the others with respect to FFA (0 24 mmol/l) and glycerol (0 06 mmol/l)

Cord blood samples were obtained from five children whose mothers had suffered from preeclampsia Three of these children—two of whom were SGA—had a normal Apgar score and had moderately increased triglyceride values (mean 0 72 mmol/l)

Twelve infants suffered from slight asphyxia Seven of them were AGA and their mean values for FFA glycerol and triglycerides (0 18 0 08 and 0 43 mmol/l respectively) did not differ from those found in infants without asphyxia Four were SGA and had high triglyceride values (2 07 1 24 1 58 and 0 68 mmol/l respectively) and two had high FFA values (0 33 and 0 32 mmol/l)

Only seven infants all of whom had very low birth weight (mean 1486 g mean gestational age 31 2 weeks) had severe asphyxia Their mean triglyceride FFA and glycerol values (0 50 0 22 and 0 07 mmol/l respectively) did not differ from those found in infants without asphyxia

DISCUSSION

The main object of this study was to investigate whether the concentrations of FFA triglycerides and glycerol were influenced by birth weight and/or gestational age With respect to AGA infants it was found that apart from a slightly lower FFA concentration in babies with a gestational age of ≤35 weeks no such influence could be shown Cord blood triglyceride levels in preterm babies have been studied by Fosbrooke & Wharton (5) who found lower values in preterm (≤36 weeks) AGA infants than in term babies and by Sabata et al (12) who found similar values in premature (≤37 weeks) and in term babies It was not stated whether SGA babies were excluded from the latter study Previously reported FFA levels have shown similar values for term babies and preterm babies (12) or preterm AGA babies (6) Although it is difficult to compare these results it might be concluded that for AGA infants of a gestational age of >35 weeks FFA triglyceride and glycerol levels are independent of gestational age and birth weight The smaller premature babies might have slightly lower triglyceride and/or FFA levels

The results were different in the SGA babies Compared with AGA babies the SGA babies had higher FFA and triglyceride levels and an increase in FFA and triglyceride levels was seen with increasing gestational age Compared with term babies of normal birth weight SGA babies had higher FFA values but the difference between mean triglyceride levels was not statistically significant In the study by Fosbrooke & Wharton (5) higher triglyceride values were found in SGA babies compared with both preterm and term AGA babies These results as well as those of the present study show marked inter individual variations in triglyceride values This may well reflect that the SGA babies are an inhomogeneous group with regard to duration and cause of the intrauterine malnutrition Support for the assumption that low birth weight for gestation is a significant factor with regard to hypertriglyceridemia may be found in the study by Tsang et al (13) who found that six SGA babies all had hypertriglyceridemia and it is in agreement with the correlation found by Andersen & Friis Hansen (1) between hypertriglyceridemia and placental insufficiency

In a study comprising AGA SGA and term babies Harris (6) found similar FFA values in all three groups No obvious explanation of why his results are in contrast to those of the present study has been found

The present study does not confirm the observation by Tsang et al (13) and by Andersen & Friis Hansen (1) of a correlation between low Apgar score and other signs of fetal distress and hypertriglyceridemia Both these studies were mainly concerned with term infants of normal birth weight However no distinction was made between dysmature and mature babies in the asphyxiated groups In

Table 3 *Concentrations of triglycerides FFA and glycerol in umbilical venous blood from AGA and SGA infants*

	n	Triglycerides (mmol/l)		FFA (mmol/l)		Glycerol (mmol/l)	
		Mean	S D	Mean	S D	Mean	S D
AGA	36	0.47	0.19	0.21	0.08	0.07	0.04
SGA	20	0.61	0.29	0.30[b]	0.15	0.06	0.04
p values *t* test		<0.05		<0.01		>0.05	

n=38 [b] *n*=24

When SGA infants with a gestational age of 38–41 weeks were compared with term infants with a birth weight of >3 000 g (Table 1) significantly higher FFA values were found among the SGA infants (0.35 mmol/l versus 0.24 mmol/l, *t* test $p<0.01$) The triglyceride values were also higher in SGA infants (0.68 mmol/l) but the difference was not significant as evaluated by the *t* test

A comparison of AGA and SGA infants of 35–38 weeks gestation did not reveal any significant differences between mean values of FFA triglyceride and glycerol concentrations although SGA infants had marginally higher FFA and triglyceride values (AGA/SGA infants FFA 25/29 mmol/l triglycerides 49/59 mmol/l)

An attempt to find a correlation between concentrations of triglycerides and FFA and the degree of intrauterine malnutrition (expressed as

$$\left(\frac{\text{birth weight}\times 100}{\text{mean birth weight for gestational age}}\right)$$

in SGA infants did not reveal any significant correlation

Eight babies with a mean birth weight of 2 213 g and a mean gestational age of 37.3 weeks were delivered by Caesarean section and did not suffer from asphyxia Five of these were SGA Cord blood concentrations of triglycerides and FFA (0.54 mmol/l and 0.23 mmol/l) did not differ from the values obtained from infants born by spontaneous vaginal birth The concentration of glycerol was found to be lower for infants born by Caesarean section than for those born by vaginal birth (0.05 mmol/l versus 0.08 mmol/l $p<0.05$)

Fourteen infants (10 AGA two SGA two of uncertain gestational age) with a mean birth weight of 2 314 g and a mean gestational age of 36.2 weeks were born by provoked labour using synticinon papaverin drop and with a normal Apgar score These infants had a mean triglyceride value that was slightly lower (0.42 mmol/l) than that found in infants born by spontaneous labour but the difference was not

ENDOCRINOLOGICAL INVESTIGATION OF PITUITARY CONADAL AXIS IN THALASSEMIA MAJOR

CH ANOUSSAKIS D ALEXIOU D ABATZIS and G BECHRAKIS

From the Endocrinological Department of the Aglaia Kyriakou Children s Hospital Athens Greece

ABSTRACT Anoussakis Ch Alexiou D Abatzis D and Bechrakis G (Endocrinological Department of the Aglaia Kyriakou Children s Hospital Athens Greece) Endocrinological investigation of pituitary gonadal axis in Thalassemia Major Acta Paediatr Scand 66 49 1977.—A study of the pituitary gonadal axis was undertaken in 18 male patients with thalassemia major and 41 normal males in order to define the cause of the sexual infantilism frequently seen in children affected by this illness The plasma testosterone level was measured before as well as after stimulation by human chorionic gonadotropin (HCG) Serum gonadotropin level was also determined during prepubertal pubertal and post pubertal age Significant findings were an insufficient secretion of gonadotropins as well as low testosterone level in patients of pubertal and post pubertal age A normal response of testes to HCG stimulation was also observed

KEY WORDS Sexual infantilism hemoglobinopathies testosterone gonadotropin

It is well known that patients with thalassemia major often show some complete sexual infantilism (2 3 4 6 7 9) However its cause remains until now undetermined The few reports on sexual immaturity of patients with thalassemia major were inconclusive about this point The present study must be considered as an attempt to elucidate the endocrine dysfunction responsible for the sexual infantilism of these patients

MATERIALS AND METHODS

Our material includes 18 male patients with thalassemia major (Table 1) and 41 normal males who served as controls The above material is divided into the following study groups

I Males prepubertal age

Patients In 9 patients 3 / to 11 / years old (mean age 6 / the plasma testosterone level was measured before and after human chorionic gonadotropin (HCG) stimulation of the testes The serum pituitary gonadotropins (FSH and LH) were also determined

Controls In 18 normal children / ₂ to 11 / ₂ years old (mean age 7 /) the plasma testosterone level was as above measured before and after stimulation of the testes In another 15 normal children 3 to 10 / ₂ years old (mean age 5³/ ₂) the serum pituitary gonadotropins (FSH and LH) were determined

II Males pubertal and postpubertal age

Patients The level of the serum pituitary gonadotropins was measured in 9 patients without any sign of puberty belonging to grade I of the classification of Tanner (13) 14³/ to 20 years old (mean age 16 / ₂) In 5 of the same patients the level of the plasma testosterone was also determined

Controls In 8 individuals 14 to 20 / years old (mean age 16 / ₂) with normal sexual maturation the level of the serum pituitary gonadotropins as well as the level of the plasma testosterone were measured

The HCG stimulation test (8) was performed as follows Three chorionic gonadotropin injections 1 500 IU each were made day after day Blood samples were obtained in the morning (10 to 1 a m) before the first injection and 4 hours after the last one After separation the plasma maintained at − 0°C

The determination of the plasma testosterone and the serum gonadotropins were made by radioimmunoassay (5)

RESULTS

I Males prepubertal age

As seen in Table 2 the patients mean plasma testosterone levels before and after HCG

agreement with the results of the present study Sabata et al (11) did not find any difference between triglyceride values for asphyxiated and non asphyxiated babies and the unchanged FFA values in asphyxia seem to be well established (6 7, 10 11) Further investigations are needed to elucidate the possible changes in triglyceride concentrations during asphyxia but from the present study it appears that one should take the nutritional status of the baby into account when evaluating the FFA and triglyceride concentrations in umbilical cord blood

ACKNOWLEDGEMENTS

spond and secrete much more testosterone In our prepubertal patients as well as in the con trols a normal increase of the testosterone level after HCG stimulation has been ob served Lassman et al (7) also reported a nor mal post HCG response of the testes in a child with thalassemia major

It was suggested (6 14) that in thalassemia major there is a primary hypogonadism However the view that the testes show immaturity or atrophy in thalassemic patients of post pubertal age derives from a few biopsies where the testicular changes may not be irreversible or complete or may be secondary to a gonadotropin deficiency at puberty The observed low excretion of urinary 17 ketosteroids is probably a consequence of the impaired adrenal function seen in thalassemia major (1 6 7)

At puberty the level of gonadotropins in creases This was found in our normal males of pubertal and postpubertal age In the pa tients of the same age the serum gonado tropins remained low at a prepubertal level This interesting finding shows that in patients with thalassemia major there is not any rise of gonadotropin secretion of hypophysis at pu berty Lassman et al (7) found low levels of LH in two adults with thalassemia major Ad ministration of clomiphene to one of them did not change their concentration Low levels of plasma testosterone were also found in two adults with thalassemia major

The low levels of testosterone observed in our patients of pubertal and postpubertal age suggest an insufficient stimulation of the testes by the hypophysis rather than damaged testes Indeed the testes HCG stimulation proved that there was a normal response up to the age of 11 years On the other hand if the low level of testosterone was due to damaged testes an important increase of the serum gonadotropins would be expected

In brief an insufficient excretion of gonado tropin by the hypophysis seems to be the cause of the sexual infantilism of the patients with thalassemia major We can further sug gest that the insufficient pituitary excretion is caused by the haemosiderosis of these patients as it was observed in the idiopathic haemo chromatosis (11 12)

stimulation, were 12 2±8 8 ng/100 ml and 148 6±50 5 ng/100 ml The mean values in the controls were 16 7±8 1 ng/100 ml and 166 0± 37 1 ng/100 ml respectively The observed differences between patients and controls before ($t=1$ 28 $p>0$ 05) and after HCG stimulation ($t=0$ 91 $p>0$ 05) were not statistically significant

Table 3 shows the values of the serum gonadotropins (FSH and LH) in the patients and the controls All the patients but one and the controls but two had plasma FSH values ≤0 4 ng/100 ml The differences here were also not significant

II *Males pubertal and postpubertal age*

Table 2 shows the plasma testosterone levels both in patients and controls of pubertal and postpubertal age It is obvious that the mean plasma testosterone level of the patients is significantly lower compared to the level of the controls ($t=14$ 4 $p<0$ 001) The mean serum gonadotropin levels are also significantly (FSH $t=5$ 48 $p<0$ 001 and LH $t=7$ 54 $p<0$ 001) lower in the patients than in the controls (Table 3) The above values compared to those found in the prepubertal age are significantly higher in the controls but without any considerable change in the patients

DISCUSSION

The testosterone level was found to be low during childhood However as shown by Saez & Bertrand (9) after stimulation by chorionic gonadotropin immature testes are able to re

LOW CONCENTRATION OF PLASMA AMINO ACIDS IN NEWBORN BABIES OF DIABETIC MOTHERS

M VEJTORP J PEDERSEN J G KLEBBE and E LUND

From Medical Department T Bispebjerg Hospital and Diabetes Centre Department of Obstetrics and Gynaecology YB Rigshospitalet Copenhagen Denmark and the Danish Institute of Protein Chemistry Horsholm Denmark

ABSTRACT Vejtorp M Pedersen J Klebe J G and Lund E (Medical Department T Bispebjerg Hospital and Diabetes Centre Department of Obstetrics and Gynaecology YB Rigshospitalet Copenhagen Denmark and the Danish Institute of Protein Chemistry Horsholm Denmark) Low concentration of plasma amino acids in newborn babies of diabetic mothers Acta Paediatr Scand 66 53 1977.—Plasma amino acid concentrations were measured in maternal peripheral vein and in umbilical vein and artery at birth (caesarean section) in 6 diabetic and 5 non-diabetic pregnancies The mean birth weight in the control group amounted to 3 9 kg as oversize of the foetus in three cases contributed to the indication for caesarean section The infants in the diabetic group consisted of small for gestational age babies (mean weight 2 8 kg) Free amino acid levels in the normal group and in diabetic maternal blood were in agreement with previous investigations No difference in amino acid concentrations in the maternal plasma was found but the concentrations of the umbilical vein plasma were significantly lower in the diabetic group Foetal hyperinsulinaemia may be a cause of the low amino acid concentrations Besides abnormalities of the placenta and maternal vascular complications increase and the mean birth weights decrease significantly through the White classes Conditions of impairment of placental transfer of amino acids may thus be present Characteristic features of the foetus may be consistent with the hypothesis as follows The foetus in diabetic pregnancy is in varying degree exposed to an oversupply of glucose hyperinsulinaemia imbalanced uptake and a slightly diminished supply of amino acids

KEY WORDS Diabetes mellitus newborn infant amino acids

The results of the few measurements of foetal and maternal concentrations of amino acids at birth in diabetic series have been conflicting (3 4 8 18)

We describe here a study of the concentrations of free amino acids in maternal peripheral venous plasma and in umbilical venous and arterial plasma at birth in a series of diabetic and non-diabetic pregnancies A hypothesis as regards the size at birth of infants of diabetic mothers (IDM) is advanced

PATIENTS AND METHODS

Patients

The material comprised a diabetic group of six mothers a non-diabetic group of five mothers and their newborn infants The diabetic series was nearly consecutive Two pregnancies belonged to White class B and four to class D (?0) The non-diabetic series was not consecutive The pregnancies were uneventful The urinary oestriol excretion was normal in the diabetic as well as in the control group

All of the infants were delivered by caesarean section The indications in the diabetic series (besides diabetes) were previous caesarean section (two) unsuccessful in

Table 1 *Clinical data*

Mean and range

Group	Maternal age (years)	Gestational age (weeks)	Birth weight (kg)	Birth length (cm)	Placental weight (g)
Diabetic	25 8	37 7	2 8	49 3	730
(*N*=6)	23–31	36–39	2 5–3 6	46–53	470–1 100
Non-diabetic	28 0	39 6	3 9	52 4	667
(*N*=5)	25–32	37–41	3 2–4 9	51–55	480– 970

duction (two) breech presentation (one) and foetal tachy cardia (one) In the control group the indications were contracted pelvis and previous section (one) contracted pelvis and oversized foetus (two) breech presentation and oversized foetus (one) and placenta previa (one) In all cases the anaesthesia was performed with nitrous oxi deoxygen after premedication with atropine and induction with enibomalsodium (Narcodorm) and succinylcholine The operations were done in the morning between 8 45 and 10 00 with one exception (at 2 50 p m in a diabetic) At 1 min Apgar scores were 4–10 in IDM and 2–9 in the control group at 5 min 9–10 in both groups No neonatal deaths occurred

Table 1 summarises maternal age gestational age birth weight birth length and placental weight

In the control group the mean birth weight amounted to 3 9 kg because presumed oversize of the foetus con tributed to the indication for caesarean section in three cases However the non-diabetic mother of the baby with a birth weight of 4 9 kg had a normal glucose tolerance test in the puerperium and also in a previous pregnancy and the mother of a baby with a birth weight of 4 4 kg was non glucosuric non-obese and without diabetes in the family The amino acid ratios F/M (concentrations in umbilical venous plasma/maternal plasma) of these two patients were in the middle of the values for the control group

Generally the birth weight of IDM is larger than that of normals (16) Consequently an IDM with a gestation time of 36–39 weeks and a birth weight of less than 2 8 kg is less than the 10 percentile and thus a small for gestational age baby (10) IDM constitutes a most inhomogenous population also inside one White class and the present series happened to comprise low weight babies with a mean birth weight of 2 8 kg or about 0 7 kg lower than usual found in our material (16) This is of importance in comparing the foetal amino acid concentrations in the present series with those of others

The mean gestational age was shorter in IDM but not significantly so Besides amino acid levels in normal pregnancies remain constant during the last trimester and into the postterm period in the mother and the foetus (23)

Methods

A few minutes before induction of anaesthesia periph eral venous blood from a maternal antecubital vein was taken in heparinized tubes From a segment of the cord insulated immediately after delivery blood was with drawn in heparinized syringes from an umbilical artery and the vein The time interval between induction of anaesthesia and withdrawal of the samples from the um bilical cord was about 5 min

After separation by centrifugation the proteins in 4 ml maternal plasma and 1 ml plasma from umbilical arterial and venous blood respectively were precipitated with picric acid which again was removed by passage through a resin column (Dowex 2–XB) The samples were then freeze-dried and stored at −18 C The maximal time interval between withdrawal of samples and freeze-drying was two hours

The samples were dissolved in sodium citrate buffer pH 2 2 and analyzed on Beckmann amino acid analyzers model 120 B and 121 Neutral and acidic amino acids were separated on ion exchange resin Type M 72 (Beckman Germany) using lithium citrate buffer as column eluant

Arginine	22	15– 28	75	54– 97

(1) The basic amino acids were separated on ion-exchange resin Type PA 35 (Beckmann USA) using sodium citrate buffer as column eluant (2) Standardized solutions of amino acids (Hamilton P AN and P B) were used for calibration after each preparation of ninhydrine and at time intervals of not more than one week The determinations were performed blindly and *in two* periods separated by a time interval of six months—due to change of location of The Danish Institute of Protein Chemistry In the first period samples from three controls and three patients with diabetes were examined No systematic difference between the determinations *performed* in the two periods was found

Twenty amino acids were determined in each sample of plasma In *one* diabetic pregnancy however the concentrations of six individual amino acids in umbilical artery blood were substituted for corresponding missing values in umb*ilical venous blood* in the calculation of the total amino acid concentration in the umbilical venous blood

The non parametric statistics were performed by the Mann-Whitney test the Wilcoxon test for pair differences and the Spearman coefficient of rank correlation The level of significance used was $p<0.05$

RESULTS

Total amino acids

In maternal peripheral venous blood the median concentration of total free amino acids in plasma was without significant difference between the diabetic and non-diabetic group In both groups of infants the median plasma concentration in umbilical venous blood was significantly higher than the maternal concentration but in IDM the median concentration was significantly lower than that in infants of non-diabetics ($p<0.05$) Also the median amino acid ratio F/M (median concentration umbilical venous plasma/maternal plasma) was significantly lower in the IDM ($p<0.01$ Table 2)

Individual amino acids

Free amino acid concentrations in maternal and umbilical venous plasma are shown for the non-diabetic group in Table 3 and for the diabetic group in Table 4 The individual amino acid concentrations in maternal plasma did not show any significant difference between the two groups In the groups taken together the concentrations of amino acids were significantly higher in umbilical venous plasma

Table 4 *Amino acid concentrations in maternal peripheral venous and umbilical venous plasma in the diabetic group*

than in maternal plasma with the exceptions that no significant difference in concentration was found for methionine aspartic acid asparagine half cystine and glutamine and that the concentration of glutamic acid was significantly higher in the maternal plasma (Tables 3 and 4) In general the individual amino acid concentration was lower in IDM than in normal infants but significantly so only for glutamic acid glycine and leucine When however an IDM/N ratio (median concentration in umbilical venous plasma at delivery in IDM/normal baby) for the individual amino acids was calculated the ratio was below 1 0 in no less than 18 out of 20 amino acids (Fig 1)

Also all of the F/M ratios for individual amino acids were lower in IDM than in the normal group but insignificantly so (Fig 2)

In the total material a tendency to higher concentrations of total and individual amino acids in umbilical venous than in umbilical artery plasma was found but a statistically significant difference was seen only for half cystine methionine and phenylalanine Contrarywise the concentration of glutamic acid was significantly higher in the umbilical artery plasma

No significant correlation was found either in the IDM or in the control group between birth weight and F/M ratio for total amino acids but the series is small

DISCUSSION

The concentrations found in this series of total free amino acids in non-diabetic and diabetic maternal blood and in normal infants and a F/M ratio of 1 9 in normals do not differ remarkably from those previously found (4 8 9,13) although as mentioned the mean birth weight amounted to 3 9 kg in the non diabetic group

A conspicuous result of this study was the demonstration of a significantly lower median concentration of free amino acids in umbilical venous plasma and a significantly lower F/M ratio in IDM compared with babies of non diabetic mothers

Previously the same result has been reported by Butterfield & O Brien (3) in one dia

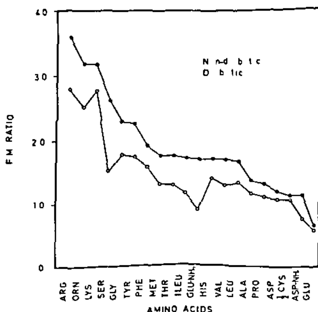

Fig 2 Ratios F/M (median concentration umbilical venous plasma/maternal plasma) of individual amino acids

betic and one prediabetic pregnancy and by Reisner et al (18) in 6 IDM although by extrapolation These findings however contrast with those of Ghadimi & Pecora (8) (three patients with advanced diabetes) and Cockburn et al (4) who found no difference in total maternal or foetal amino acid concentrations from normals Thus Cockburn et al calculated the F/M ratio to 1 6 in the normal as well as the diabetic series However their 9 IDM (White class B 1 C 5 D 2 F 1) were large for date babies with a mean weight of 3 8 kg or 1 kg more than that in the present series This difference in the two small series is not unnatural but should be kept in mind

It is of interest to point out that low F/M ratios also have been demonstrated in small for gestational age babies of mothers with a higher than normal maternal level (4 13) while in the present investigation the low ratio depended on a lower than normal foetal level

From previous investigations in human and more extensively in sheep and guinea pigs information has been gained concerning placental transfer of amino acids In general the transport is an active process operating against a concentration gradient The foetal supply depends on the active transport at the placental membrane the maternal blood flow and to a lesser extent the maternal concentration of amino acids The foetal pattern however seems to be related to foetal metabolism more than to the maternal supply (11 19 21 22)

The low foetal concentration of amino acids seen in IDM in this series may thus be due to an abnormal foetal amino acid metabolism and/or to a failure of the active transport at the placental membrane and/or to a decreased placental blood flow the consequence of which would be a lack of supply of amino acids to the foetus

Hyperinsulinaemia is a characteristic feature of IDM (16) Insulin promotes the transport of amino acids over cell membranes especially as regards the branched-chain amino acids valine leucine and isoleucine These amino acids are mainly if not exclusively metabolised in muscle A low concentration could be a consequence of hyperinsulinaemia In this series the ratio IDM/N was below 1 0 in 18 of 20 amino acids but only the concentrations of leucine glutamic acid and glycine was significantly lower in IDM However an insulin effect on the aminogram in IDM seems probable

The problem is whether there in addition to the effect of hyperinsulinaemia also is impairment of placental amino acid transfer resulting in foetal protein malnutrition and small size at birth From the present investigation of concentrations it is of course impossible to infer an impaired placental transfer Characteristic features of IDM may however point to a slight protein malnutrition

1) IDM are overweight predominately due to fat (7 15) but there is a significant decrease in the mean birth weight through the White classes (16)

2) Pathologic features of the diabetic placenta (16) and maternal vascular complications increase through the White classes

3) Although the total protein content of IDM seems normal (7 14) the serum protein concentration is decreased (5) and the development of ossification centers (17) muscles and bones (15) is retarded in relation to gestational age

4) The amino acid pattern in subclinical kwashiorkor (12) which according to the simplest concept is caused by a high carbohydrate supply and protein malnutrition has similarities with the pattern found in IDM (for details see (16))

The features of IDM may thus be consistent with oversupply of glucose hyperinsulinaemia imbalanced uptake and a slightly reduced supply of amino acids The low birth weight and low amino acid concentration in the present series as well as the normal amino acid concentration in the large babies in the series of Cockburn et al (4) may be an expression of this hypothesis

The hypothesis can be tested The concen

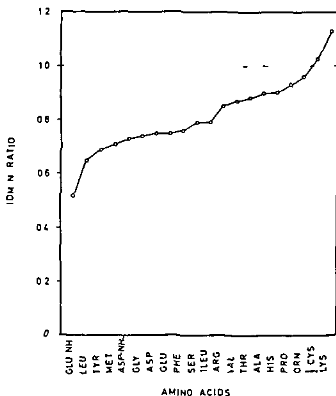

Fig 1 Ratios IDM/N (median concentration umbilical venous plasma in IDM/normal baby) of individual amino acids ($\bar{x}$ $N=5$)

than in maternal plasma with the exceptions that no significant difference in concentration was found for methionine aspartic acid asparagine half cystine and glutamine and that the concentration of glutamic acid was significantly higher in the maternal plasma (Tables 3 and 4) In general the individual amino acid concentration was lower in IDM than in normal infants but significantly so only for glutamic acid glycine and leucine When however an IDM/N ratio (median concentration in umbilical venous plasma at delivery in IDM/normal baby) for the individual amino acids was calculated the ratio was below 1 0 in no less than 18 out of 20 amino acids (Fig 1)

Also all of the F/M ratios for individual amino acids were lower in IDM than in the normal group but insignificantly so (Fig 2)

EFFECT OF CONTINUOUS POSITIVE AIRWAY PRESSURE BREATHING ON CARDIORESPIRATORY FUNCTION IN INFANTS WITH RESPIRATORY DISTRESS SYNDROME

V Y H YU and P ROLFE

From the Department of Paediatrics University of Oxford John Radcliffe Hospital Oxford England

ABSTRACT Yu V Y H and Rolfe P (Department of Paediatrics University of Oxford John Radcliffe Hospital Oxford England) Effects of continuous positive airway pressure breathing on cardiorespiratory function in infants with respiratory distress syndrome Acta Paediatr Scand 66 59 1977.—A method of investigating the cardiorespiratory responses to continuous positive airway pressure (CPAP) in infants with respiratory distress syndrome is described All measurements were made immediately before and within five minutes of application or any change in level of CPAP Ventilation was derived from a pneumotachograph and dynamic compliance calculated We have also measured arterial pH oxygen and carbon dioxide tensions arterial blood pressure and central venous pressure Arterial oxygen tension increased in association with a decrease in the alveolar arterial oxygen gradient No consistent changes occurred in pH or carbon dioxide tension Heart rate and mean arterial blood pressure remained the same but the arterial pulse pressure narrowed and the increase in central venous pressure averaged 17% of the applied airway pressure There were less variations in both tidal volumes and instantaneous respiratory rates with CPAP compared with spontaneous breathing without CPAP The respiratory rate decreased but there were no consistent changes in tidal volume resulting in a lesser reduction of minute ventilation Dynamic compliance decreased on CPAP With correct use of CPAP and improvement in oxygenation generally occurs without obvious adverse cardiorespiratory effects CPAP must nevertheless be used cautiously and in conjunction with close monitoring because when the appropriate pressures are exceeded it is possible that both circulatory and ventilatory function might be severely compromised

KEY WORDS Preterm infants respiratory distress syndrome continuous airway pressure breathing

Continuous positive airway pressure (CPAP) is an established method of ventilatory assistance in severe respiratory distress syndrome (RDS) in newborn infants Since the first report by Gregory et al (12) on the treatment of RDS with CPAP a great number of clinical studies have taken place However little information is available regarding the effects of CPAP upon the cardiovascular system or on the ventilatory pattern and lung mechanics in infants with RDS

In the present paper a method of investigating some of these effects is described We have studied the following parameters of cardiorespiratory function in infants with RDS before and after the application of CPAP as well as during two or more levels of CPAP arterial pH oxygen and carbon dioxide tensions (P_{aO_2} and P_{aCO_2}) heart rate arterial blood pressure central venous pressure respiratory rate tidal volume minute ventilation and dynamic compliance

trations of amino acids should be lower in a group of White classes D+F than in one of White classes B+C infants with a significant difference in birth weight The placental trans fer of amino acids which may require whole blood determinations (6) might be experi mentally investigated

From the Department of Paediatrics University of Oxford John Radcliffe Hospital Oxford England

ABSTRACT Yu V Y H and Rolfe P (Department of Paediatrics University of Oxford John Radcliffe Hospital Oxford England) Effects of continuous positive airway pressure breathing on cardiorespiratory function in infants with respiratory distress syndrome Acta Paediatr Scand 66 59 1977 —A method of investigating the cardiorespiratory responses to continuous positive airway pressure (CPAP) in infants with respiratory distress syndrome is described All measurements were made immediately before and within five minutes of application or any change in level of CPAP Ventilation was derived from a pneumotachograph and dynamic compliance calculated We have also measured arterial pH oxygen and carbon dioxide tensions arterial blood pressure and central venous pressure Arterial oxygen tension increased in association with a decrease in the alveolar arterial oxygen gradient No consistent changes occurred in pH or carbon dioxide tension Heart rate and mean arterial blood pressure remained the same but the arterial pulse pressure narrowed and the increase in central venous pressure averaged 17% of the applied airway pressure There were less variations in both tidal volumes and instantaneous respiratory rates with CPAP compared with spontaneous breathing without CPAP The respiratory rate decreased but there were no consistent changes in tidal volume resulting in a lesser reduction of *minute ventilation* Dynamic compliance decreased on CPAP With correct use of CPAP and improvement in oxygenation generally occurs without obvious adverse cardiorespiratory effects CPAP must nevertheless be used cautiously and in conjunction with close monitoring because when the appropriate pressures are exceeded it is possible that both circulatory and ventilatory function might be severely compromised

KEY WORDS Preterm infants respiratory distress syndrome continuous airway pressure breathing

Continuous positive airway pressure (CPAP) is an established method of ventilatory assistance in severe respiratory distress syndrome (RDS) in newborn infants Since the first report by Gregory et al (12) on the treatment of RDS with CPAP a great number of clinical studies have taken place However little information is available regarding the effects of CPAP upon the cardiovascular system or on the ventilatory pattern and lung mechanics in infants with RDS

In the present paper a method of investigating some of these effects is described We have studied the following parameters of cardiorespiratory function in infants with RDS before and after the application of CPAP as well as during two or more levels of CPAP arterial pH oxygen and carbon dioxide tensions (P_{aO_2} and P_{aCO_2}) heart rate arterial blood pressure central venous pressure respiratory rate tidal volume minute ventilation and dynamic compliance

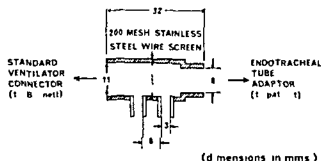

Fig 1 Design of pneumotachograph

MATERIAL AND METHODS

Six newborn infants were studied on ten occasions when they were breathing at two or more levels of CPAP All were suffering from respiratory distress according to the standard criteria (9) and had chest X rays that were compatible with hyaline membrane disease An arterial oxygen tension below 8 kilopascals while breathing 60% oxygen was the indication for commencing CPAP Further data on the infants are presented in Table 1 CPAP between 5–15 hectopascals was applied by means of an endotracheal tube Etches et al (10) have described our technique of administering CPAP using the Bennett PR2 Special ventilator

All the infants had indwelling umbilical arterial and venous catheters for routine monitoring The arterial catheter which was placed in the descending aorta was used for blood pressure measurements as well as blood sampling for pH P_{aO_2} and P_{aCO_2} The venous catheter was positioned in the inferior vena cava above the diaphragm as determined from X ray and from pressure curves (1)

Respiratory air flow rate was measured by the pneumotachograph Fig 1 shows the design of the pneumotachograph which was made of perspex and suitable for use in newborn infants during assisted ventilation The larger end fitted into a Bennett ventilator connector and the smaller and fitted into a endotracheal tube adaptor The dead space of the pneumotachograph was 1 8 ml and it had a low resistance of 1 6 hPa per 1 per s It has a 200 mesh stainless steel wire screen of 0 95 cm² as the resistor The peak flows attained by the infants (59 ml per s in inspiration 53 ml per s in expiration) fell well within the range shown to be linear (0 to 150 ml per s) for the instrument (Fig 2) We found no problems with condensation of water vapour on the screen resistor during the brief study periods (1 to 1 2 kiloseconds) no heating of the pneumotachograph was necessary since the instrument was used in the infant s incubator which was maintained at 30 C The pneumotachograph was attached to a differential pressure transducer (Elema Schoenander Differential Pressure Transducer Type EMT) the output of which was integrated electronically to obtain tidal volume Calibrations were carried out immediately after each study using a gas mixture of the same temperature and composition as that inspired by the infant during the study (13) In all our infants size 14 endotracheal tubes were used to minimise the problem of

leaking around the tube during the study When such leaks occurred they were recognisable from a displacement in the position of the zero flow and a ramp function (i e a progressive displacement of base line from the horizontal) in the tidal flow recording Studies in which such errors were apparent were excluded from the present analysis

Oesophageal pressure was measured by means of a No 5 F G polyvinyl feeding tube the tip of which was covered by a latex balloon (length 5 cm diameter 8 mm thickness 0 014 mm) This was inserted through the mouth to the distal third of the oesophagus The volume of air in the balloon was 0 2–0 3 ml within which range pressure changes due to the elastic properties of the balloon were shown to be negligible (19) The pressure transducer (Bell and Howell type 4–422) which was used to measure oesophageal pressure was calibrated with a water manometer immediately after the study The difference in oesophageal pressure at end-expiration with and without CPAP was used to estimate the effect of CPAP on intrathoracic pressure

The inspired oxygen concentration was maintained at the level used initially for clinical management and kept constant for the duration of the study The infant was

studied for a period of 0 3 kiloseconds at each given level of CPAP The direction of the change in CPAP was varied to avoid effects due to sequential changes During the last 60 s of each study period an arterial blood sample was obtained for the determination of pH P_{O_2} and P_{aCO_2} Continuous recordings of central venous pressure arterial blood pressure respiratory air flow tidal volume and oesophageal pressure were made on a 6 channel polygraph (type M19 Devices Ltd London England) but the values reported here are those recorded between 180–300 s at a given level of CPAP Heart rate was counted from the tidal volume recording Mean tidal volume and minute ventilation were calculated from all the breaths in the same 60 s

For the purpose of calculating compliance 10 breaths were used the tidal volumes of which were within 1 ml of the mean for the whole of the selected 60 s Dynamic compliance was calculated from these breaths by dividing the tidal volume by the change in oesophageal pressure at the time of zero flow (7) The alveolar arterial oxygen difference (A aD_{O_2}) was calculated by using the alveolar air equation and assuming a respiratory quotient of 0 8

$$PA_{O_2} = (P_B - P_{H_2O}) F_{IO_2} - PA_{CO_2}\left(F_{IO_2} + \frac{1-F_{IO_2}}{R}\right)$$

Where PA_{O_2} is alveolar oxygen tension F_{IO_2} is inspired oxygen concentration PA_{CO_2} is alveolar carbon dioxide tension assumed to be the same as arterial carbon dioxide tension R is respiratory quotient

RESULTS

The cardiorespiratory responses to CPAP are summarised in Table 2 and Fig 3 No consistent changes occurred in pH and P_{aCO_2} Arterial oxygenation improved in all infants on CPAP as shown by a significant increase in P_{aO_2} ($p<0\ 005$) and decrease in A aD_{O_2} ($p<0\ 01$) as asserted by the *t* test for pairs

No changes occurred with heart rate or mean blood pressure The narrowing of the pulse pressure with CPAP was shown to be significant ($p<0\ 05$) as was the rise in central venous pressure ($p<0\ 02$) The average increase in central venous pressure was 17% of the applied airway pressure This compared with an average value of 32% increase in intra thoracic pressure as measured by the oesophageal balloon

The respiratory rate decreased significantly ($p<0\ 005$) but no consistent changes in tidal volume were observed resulting in a smaller reduction of minute ventilation ($p<0\ 1$) Dynamic compliance decreased the change being statistically significant

Figs 4 and 5 shows the breath by breath plot of tidal volume and respiratory rate for the 60 s periods with and without CPAP in one of the infants studied There was considerable variation in both tidal volume and respiratory rate during spontaneous breathing without CPAP In contrast a more regular respiratory trace was obtained after application of CPAP and there was much less variability on a breath to breath basis

Variance comparisons for instantaneous tidal volume and respiratory rate were done

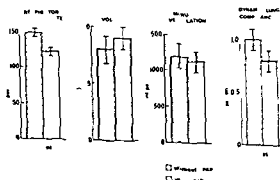

Fig 3 Effect of CPAP on respiratory rate tidal volume minute ventilation and dynamic compliance

RESULTS

The cardiorespiratory responses to CPAP are summarised in Table 2 and Fig 3 No consistent changes occurred in pH and P_{CO_2} Arterial oxygenation improved in all infants on CPAP as shown by a significant increase in P_{aO_2} ($p<0\ 005$) and decrease in A aD_{O_2} ($p<0\ 01$) as asserted by the *t* test for pairs

No changes occurred with heart rate or mean blood pressure The narrowing of the pulse pressure with CPAP was shown to be significant ($p<0\ 05$) as was the rise in central venous pressure ($p<0\ 02$) The average increase in central venous pressure was 17% of the applied airway pressure This compared with an average value of 32% increase in intra thoracic pressure as measured by the oeso phageal balloon

The respiratory rate decreased significantly ($p<0\ 005$) but no consistent changes in tidal volume were observed resulting in a smaller reduction of minute ventilation ($p<0\ 1$) Dynamic compliance decreased the change being statistically significant

Figs 4 and 5 shows the breath by breath plot of tidal volume and respiratory rate for the 60 s periods with and without CPAP in one of the infants studied There was considerable variation in both tidal volume and respiratory rate during spontaneous breathing without CPAP In contrast a more regular respiratory trace was obtained after application of CPAP and there was much less variability on a breath to breath basis

Variance comparisons for instantaneous tidal volume and respiratory rate were done

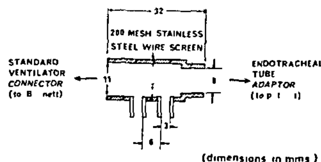

Fig 1 Design of pneumotachograph

MATERIAL AND METHODS

Six newborn infants were studied on ten occasions when they were breathing at two or more levels of CPAP All were suffering from respiratory distress according to the standard criteria (9) and had chest X rays that were compatible with hyaline membrane disease An arterial oxygen tension below 8 kilopascals while breathing 60% oxygen was the indication for commencing CPAP Further data on the infants are presented in Table 1 CPAP between 5–15 hectopascals was applied by means of an endotracheal tube Etches et al (10) have described our technique of administering CPAP using the Bennett PR2 Special ventilator

All the infants had indwelling umbilical arterial and venous catheters for routine monitoring The arterial catheter which was placed in the descending aorta was used for blood pressure measurements as well as blood sampling for pH P_O and P_{CO_2} The venous catheter was positioned in the inferior vena cava above the diaphragm as determined from X ray and from pressure curves (1)

Respiratory air flow rate was measured by the pneumotachograph Fig 1 shows the design of the pneumotachograph which was made of perspex and suitable for use in newborn infants during assisted ventilation The larger end fitted into a Bennett ventilator connector and the smaller and fitted into a endotracheal tube adaptor The dead space of the pneumotachograph was 1 8 ml and it had a low resistance of 1 6 hPa per 1 per s It has a 200 mesh stainless steel wire screen of 0 95 cm² as the resistor The peak flows attained by the infants (59 ml per s in inspiration 53 ml per s in expiration) fell well within the range shown to be linear (0 to 150 ml per s) for the instrument (Fig 2) We found no problems with condensation of water vapour on the screen resistor during the brief study periods (1 to 1 2 kiloseconds) no heating of the pneumotachograph was necessary since the instrument was used in the infant s incubator which was maintained at 30°C The pneumotachograph was attached to a differential pressure transducer (Elema Schoenander Differential Pressure Transducer Type EMT) the output of which was integrated electronically to obtain tidal volume Calibrations were carried out immediately after each study using a gas mixture of the same temperature and composition as that inspired by the infant during the study (13) In all our infants size 14 endotracheal tubes were used to minimise the problem of leaking around the tube during the study When such leaks occurred they were recognisable from a displacement in the position of the zero flow and a ramp function (i e a progressive displacement of base line from the horizontal) in the tidal flow recording Studies in which such errors were apparent were excluded from the present analysis

Table 1 *Clinical data of six infants treated with CPAP*

	Mean±S E M	Range
Gestation (weeks)	33 5 ±1 3	29– 38
Birthweight (grams)	2 153±236	1 580–3170
Age when studied (kiloseconds)	137±43 6	18– 331
Inspired oxygen (per cent)	72±5 9	55– 95
Applied CPAP (hectopascals)	9±1 3	5– 15

Oesophageal pressure was measured by means of a No 5 F G polyvinyl feeding tube the tip of which was covered by a latex balloon (length 5 cm diameter 8 mm thickness 0 014 mm) This was inserted through the mouth to the distal third of the oesophagus The volume of air in the balloon was 0 2–0 3 ml within which range pressure changes due to the elastic properties of the balloon were shown to be negligible (19) The pressure transducer (Bell and Howell type 4–422) which was used to measure oesophageal pressure was calibrated with a water manometer immediately after the study The difference in oesophageal pressure at end-expiration with and without CPAP was used to estimate the effect of CPAP on intrathoracic pressure

The inspired oxygen concentration was maintained at the level used initially for clinical management and kept constant for the duration of the study The infant was

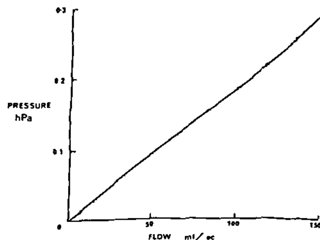

Fig 2 Linear relationship between pressure change and flow across pneumotachograph

percentage of CPAP may be transmitted to the intrathoracic space resulting in an increasing embarrassment of the circulation

We have found an increase in P_{aO_2} and a decrease in A aD$_{O_2}$ without a consistent change in P_{aCO_2} The increase in P_{aO_2} was thought to be a result of reducing right to left shunting of blood through the lung secondary to expansion of perfused but collapsed alveoli (12) However in the study of Bancalari et al (2) no correlation was found between the in crease in functional residual capacity and the change in P_{aO_2} These authors suggested that there is also a modification of extra pulmonary shunts secondary to a drop in pulmonary vas cular resistance They may be achieved by an increase in P_{aO_2} in lung volume or in vascular transmural pressure all of which are known to reduce pulmonary vascular resistance (5 16 24)

Previous observations on the effects of CPAP on respiratory rate showed an increase (11) no change (7) and a decrease in rate (2) We found a decrease in respiratory rate with CPAP in all our infants but the effect on tidal volume varied In Bancalari s series (2) a drop in both respiratory rate and tidal volume was observed In their study continuous thoracic negative pressure was used instead of CPAP and their values of tidal volume were meas ured over 10 to 15 s periods of regular breath ing only Studies of acute exposure of con scious adults to CPAP showed a fall in tidal volume (11 22) although prolongation of breathing against continuous positive pressure was associated in adults with a progressive rise in tidal volume (11) The small reduction in minute ventilation in association with a con stant alveolar ventilation as indicated by the P_{CO_2} data suggested a decrease in dead space ventilation

The decrease in dynamic compliance with CPAP is particularly significant because the decrease in respiratory rate during CPAP tended to increase compliance Furthermore CPAP has been reported to increase in func tional residual capacity (2 25) The observed reduction in dynamic compliance therefore im plies that with CPAP in addition to expansion of previously collapsed alveoli some of the relatively normal areas of the lung were prob ably over inflated as well This would have the effect of bringing these units to the flat tened portion of their pressure volume curve (14)

It has always been our clinical impression that CPAP resulted in more regular respira tion Objective assessment of breathing pat tern however has not been resported with CPAP Gregory et al (12) observed that 10 in fants with RDS had periods of apnoea before CPAP but after it was applied respirations were described as regular We have shown in this study less variability in individual breaths for both tidal volume and respiratory rate dur ing CPAP compared with the irregular pat terns during spontaneous breathing without CPAP This change in ventilatory pattern may be a significant factor in the improvement of alveolar ventilation The elimination of breaths with very low tidal volumes during regular periods of respiration may have the effect of decreasing dead space ventilation during CPAP Furthermore the presence of such gross differences in ventilatory patterns make it even more obvious that reliable measurements of ventilation will require re cording periods of more than a few seconds or a few breaths

The number of observations in this study were few The results must therefore be inter preted with caution A correct diagnosis of respiratory distress syndrome or other dis eases with lung of low compliance is essential before starting CPAP treatment In such clini cal situations with appropriate use of CPAP an improvement in oxygenation occurs with out obvious adverse cardiorespiratory effects CPAP must however be used cautiously and in conjunction with close monitoring because when the appropriate pressures are exceeded it is possible that both circulatory and ven tilatory functions might be severely com promised

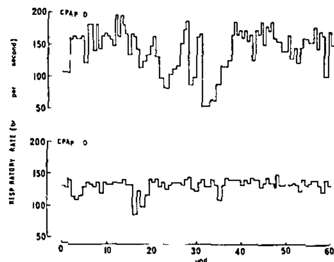

Fig 4. Breath by breath plot of respiratory rate.

for the 10 studies comparing values for the 60 s study period with and without CPAP. The results showed using analysis by the *f* test a significantly lower variance in instantaneous respiratory rate with CPAP in 7 of the 10 studies. A lower variance in instantaneous tidal volume with CPAP occurred in 9, 6 of which reached statistical significance.

DISCUSSION

The effects of an increase in transpulmonary pressure on the cardiovascular system *in the* newborn infant have not been adequately studied. Previous investigations were done mainly in adults with *normally compliant* lungs. When the airway pressure was increased, tachycardia, hypotension, a decrease in stroke volume and cardiac *output* were demonstrated in both human and animal studies (4, 8, 15, 20). In contrast little change in cardiac output was observed when 5 hectopascals was applied during expiration to the lungs of patients with pneumonia and "shock lungs" (18). The circulatory changes in adult studies were generally demonstrated at pressures greater than those employed for neonatal respiratory diseases.

No measurements of cardiac output or venous return with the use of CPAP in human infants suffering from RDS have been reported. It was assumed by Gregory et al. (12) that because the rise in oesophageal pressure with CPAP was only 20% of the pressure applied to the airway, the circulation was *probably not* appreciably compromised. Clinical observations may even suggest that infants with RDS on CPAP have an improvement of cardiovascular function coincidental with the improvement of oxygenation (6). In common with other clinical studies in which blood pressure was monitored *in some of the infants* studied, we found no significant changes in mean blood pressure with CPAP (3, 21, 23, 26). Although no obvious clinical deterioration was observed in any of our infants, the pulse pressure decreased and the central pressure increased with CPAP. Since the venous return *to the right atrium depends on the difference* in pressure between intrathoracic and extrathoracic veins, the application of CPAP can on a theoretical basis impede venous return (6, 17). It is therefore important that the use of *CPAP* in *RDS* must be approached with caution, particularly in situations of hypovolaemia and impaired cardiac output. Monitoring of arterial blood pressure and central venous pressure may be important at a time when the infant with RDS improves and the lungs become more compliant, when a greater

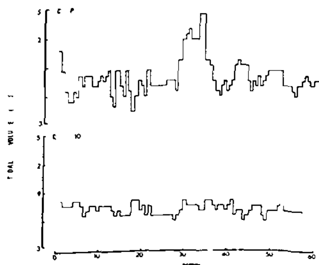

Fig 5. Breath by breath plot of tidal volume.

percentage of CPAP may be transmitted to the intrathoracic space resulting in an increasing embarrassment of the circulation

We have found an increase in P_{aO_2} and a decrease in $A\text{-}aD_{O_2}$ without a consistent change in P_{aCO_2}. The increase in P_{aO_2} was thought to be a result of reducing right to left shunting of blood through the lung secondary to expansion of perfused but collapsed alveoli (12) However in the study of Bancalari et al (2) no correlation was found between the increase in functional residual capacity and the change in P_{aO_2}. These authors suggested that there is also a modification of extra pulmonary shunts secondary to a drop in pulmonary vascular resistance They may be achieved by an increase in P_{O_2} in lung volume or in vascular transmural pressure all of which are known to reduce pulmonary vascular resistance (5 16 24)

Previous observations on the effects of CPAP on respiratory rate showed an increase (11) no change (7) and a decrease in rate (2) We found a decrease in respiratory rate with CPAP in all our infants but the effect on tidal volume varied In Bancalari s series (2) a drop in both respiratory rate and tidal volume was observed In their study continuous thoracic negative pressure was used instead of CPAP and their values of tidal volume were measured over 10 to 15 s periods of regular breathing only Studies of acute exposure of conscious adults to CPAP showed a fall in tidal volume (11 22) although prolongation of breathing against continuous positive pressure was associated in adults with a progressive rise in tidal volume (11) The small reduction in minute ventilation in association with a constant alveolar ventilation as indicated by the P_{CO_2} data suggested a decrease in dead space ventilation

The decrease in dynamic compliance with CPAP is particularly significant because the decrease in respiratory rate during CPAP tended to increase compliance Furthermore CPAP has been reported to increase in functional residual capacity (2 25) The observed reduction in dynamic compliance therefore implies that with CPAP in addition to expansion of previously collapsed alveoli some of the relatively normal areas of the lung were probably over inflated as well This would have the effect of bringing these units to the flattened portion of their pressure volume curve (14)

It has always been our clinical impression that CPAP resulted in more regular respiration Objective assessment of breathing pattern however has not been resported with CPAP Gregory et al (12) observed that 10 infants with RDS had periods of apnoea before CPAP but after it was applied respirations were described as regular We have shown in this study less variability in individual breaths for both tidal volume and respiratory rate during CPAP compared with the irregular patterns during spontaneous breathing without CPAP This change in ventilatory pattern may be a significant factor in the improvement of alveolar ventilation The elimination of breaths with very low tidal volumes during regular periods of respiration may have the effect of decreasing dead space ventilation during CPAP Furthermore the presence of such gross differences in ventilatory patterns make it even more obvious that reliable measurements of ventilation will require recording periods of more than a few seconds or a few breaths

SEASONAL INCIDENCE OF SOME CONGENITAL MALFORMATIONS IN THE CENTRAL NERVOUS SYSTEM IN SWEDEN 1965–1972

BJÖRN SANDAHL

From the Department of Obstetrics and Gynaecology Malmo General Hospital Malmo and the Department of Embryology University of Lund Sweden

ABSTRACT Sandahl B (Department of Obstetrics and Gynecology Malmo General Hospital Malmo and Department of Embryology University of Lund Sweden) Seasonal incidence of some congenital malformations in the central nervous system in Sweden 1965–1972 Acta Paediatr Scand 66 65 1977.—Seasonal trends of some congenital CNS malformations in infants born in Sweden during the years 1965 to 1972 were investigated The study is based on reports to the Swedish Register of Congenital Malformations statistics from the National Board of Health and records from Malmo General Hospital and the Hospital of Lund The malformations analysed in this study are anencephaly spina bifida aperta (with or without hydrocephalus) and isolated hydrocephalus Variations in incidence of months of birth and last menstrual period (LMP) were tested statistically in three different ways standard χ test for heterogeneity between recorded numbers of infants each calender month Edwards method and a squared sinus function all with or without correction for variations in general monthly birth rates Statistical significant seasonal variations were found for anencephaly with an LMP maximum in March and for spina bifida aperta with a maximum in July Factors which can explain such seasonality are briefly discussed

KEY WORDS Abnormalities anencephaly spina bifida hydrocephalus seasons

Many studies have been published on seasonal variations in malformation rates A critical review on early work in this field was given by Bailar & Gurian (1) The most wellknown example of seasonality in malformation rates is that found for anencephaly (2) and meningocele However there appear to be marked secular changes and also geographic differences in seasonality for this group of malformations (Table 1)

The present paper reports on an analysis of seasonality in some CNS malformation rates reported to the Swedish Register of Congenital Malformations supplemented with hospital data

MATERIAL AND METHODS

The following sources of material were used

1 The Swedish Register of Congenital Malformations Since 1965 infants born with malformations are reported from hospitals where the infants are examined by a paediatrician after birth (50 hospitals in 1965 60 in 197?) These hospitals are scattered over the greater part of the country and represent appr 65% in 1965 and 80% in 197 of the total number of births in Sweden The only excluded region is the Uppsala region (see below) This register has supplied information on the number of infants born each month with a certain malformation diagnosis Reports of such infants are divided into two groups 1) infants with only one reported malformation 2) infants with two or more simultaneous malformations For this study infants registered with only one malformation were analysed except for those with anencephaly where that diagnosis obviously dominates

2 National Board of Health collected detailed In patient statistics from hospitals in the Uppsala region 1964–1968 (3) This region was not included in the Register of Malformations until 1973 why data from the Swedish Register of Congenital Malformations were supplemented with informations from this source This source also provided information concerning gestational length of pregnancies resulting in infants with congenital malformations in the central nervous system (4)

3 Records from the Malmö General Hospital and the

Hospital of Lund (Departments of Gynaecology and Obstetrics of Pathology and Neurosurgery) These records were searched for infants born at the two hospitals during the period 1960–1973 with anencephaly spina bifida aperta or hydrocephalus Information on pregnancy length in these pregnancies was retrieved During the period 1965–1972 a number of cases were found that were not reported to the Register of Malformations—as shown by Källén & Winberg (5) these two hospitals showed a marked underreporting especially for anencephalic infants The Register material was supplemented with these cases

4 A prospective study performed in Malmo during 1963–1964 comprising appr 6400 pregnancies (6) Date of last menstrual period (LMP) and date of birth was known for all pregnancies ending with the birth of a normal infant and these data were used for estimating pregnancy length distribution (cf 7)

5 Official statistics of Sweden This source supplied information on the total number of births each calendar month for the period 1965–1972

Malformations Studied

A *Anencephaly* All infants born 1965–1972 with anencephaly reported to the Register of Congenital Malformations or to the In patient statistics from hospitals in the Uppsala region and such infants identified from hospital records in Malmo or Lund were used Only from this group were infants with more than one major malformation accepted

B *Spina bifida aperta* All infants reported to the Register of Congenital Malformations with meningocele myelomeningocele or myeloschisis were used if no other simultaneous malformation was reported the only exceptions being talipes or hydrocephalus These two malformations are not registered as separate entities in the Register when central nervous system dysraphism is present Infants with both anencephaly and spina bifida aperta were classified as anencephalic only

C *Hydrocephalus* Infants with hydrocephalus and without any other known malformation were accepted The definition of hydrocephalus which leads to the primary report is a head circumference more than 38 cm

Table 2 *Recorded monthly distribution of births of infants with some CNS malformations*
Swedish Register of Malformations 1965–1972 supplemented with some other material (see text)

	Total no	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
Anencephaly	296	27	20	8	35	26	12	26	15	20	33	28	31
Spina bifida aperta	263	18	26	21	17	32	25	23	22	26	17	17	19
Hydrocephalus	90	9	1	6	4	8	7	6	9	10	6	9	4

where no obvious explanation exists in the form of massive scalp bleeding or oedema. In dubious cases the report is accepted only after follow up. Note that hydrocephalus secondary to spina bifida aperta is only classified under the latter diagnosis.

Statistical Methods

The actual numbers of malformed infants identified each calendar month were compared by three different methods in order to discover whether random variations could explain recorded differences.

χ² test

Standard χ² tests for heterogeneity were run between recorded numbers of infants each calendar month. They are based on 11 d.f. Such tests were made both on the number of infants born each month and on the number of pregnancies begun each month (LMP dates). When corrections for changes in monthly pregnancy rates were made, χ² tests (also at 11 d.f.) were performed between the found values and the expected values at no monthly differences in malformation incidence (null hypothesis).

Edwards' method

Edwards (8) described a method for analysing seasonal changes in, for instance, malformation rates. It is much superior to the simple χ² test as it utilizes the support given by adjoining months, i.e. seasonal *trend* in the materials. Principally the method consists of fitting a sinus curve to the recorded differences between found and expected number of malformed infants each calendar month after normal transformation. This method was applied on raw monthly data and on data after correction for pregnancy length and pregnancy rates. The χ² values obtained in this method are based on d.f. The method has been criticized by Hewitt et al. (9) as it can give significant results for data that do not show a real rhythmicity.

Suggested method

A drawback with Edwards' method is that it supposes a sinus curve as a reasonable mathematical model for the recorded fluctuations, i.e. a symmetrical curve with six months of increase and six months of decrease and with maximum and minimum incidence of the same magnitude. A modification was therefore tried which allows for asymmetrical periodic change during the year. As a possible mathematical model the following equation was used:

$$Y = \alpha \sin x + \beta \cos x$$

where x is the number of the calendar month expressed in 1/12 of 360 (= one year) and α and β are coefficients. The beginning of the cyclic function—the change from low to high values—is found empirically. This function is fitted to variates made up of the differences between found and expected numbers transformed to normality by the $2\sqrt{\ }$ method. The variates will thus be $Y = 2(\sqrt{F} - \sqrt{E})$ where F is the observed number—sometimes after corrections for e.g. pregnancy length—and E is the expected values under the hypothesis of constant malformation incidence during the year (null hypothesis). As only whole months are used, the sin x values will be the following: 0, 0.5, 0.866, 1.0, 0.866, 0.5, 0, −0.5, −0.866, −1.0, −0.866 and −0.5. By using the least squares method, the following estimates of α and β can be made:

$$\alpha = \frac{1}{6}\Sigma(Y \sin x)$$

$$\beta = \frac{}{9}\Sigma(Y \sin x)$$

and the sum of squares around the function so defined is

$$\Sigma d^2 = \Sigma Y^2 - \frac{1}{6}[\Sigma(Y \sin x)]^2 - \frac{}{9}[\Sigma(Y \sin x)]^2 \quad \text{based on 9 d.f.}$$

If seasonality is disregarded, the sum of squares is

$$\Sigma d_0^2 = \Sigma[2(\sqrt{F} - \sqrt{E})]^2 \quad \text{based on 11 d.f.}$$

The difference $\Sigma d_0^2 - \Sigma d^2$, based on ? d.f., is the sum of squares eliminated by the squared sinus function and it can be evaluated with an F test against the error variance around the function, i.e.

$$F_{2,9} = \frac{(\Sigma d_0^2 - \Sigma d^2)/2}{(\Sigma d^2)/9}$$

RESULTS

Table 2 presents the raw material, namely the number of infants born each month with the different malformations discussed. It also gives the total number of infants in each category. The smallest group consists of only 90 infants with isolated hydrocephalus. However, 90 is sufficient to give expected numbers of infants each month above 5 in all χ² tests performed.

Table 3 *Seasonality of normal births (according to Sandahl 1974) Per cent of all births in Sweden 1965–1972*

Month	%	Month	%
Jan	8 20	July	8 15
Febr	8 07	Aug	7 94
March	9 64	Sept	8 07
April	9 72	Oct	7 96
May	9 23	Nov	7 28
June	8 28	Dec	7 45

Seasonality can be analysed in different ways Months of birth or months of last menstrual period (LMP) can be compared The two methods will give different results if the length of pregnancy differs between normal infants and those with the malformation in question Seasonality can also be studied with or without considering monthly fluctuation in frequency of normal births

I *Seasonality according to month of birth*

The monthly distribution of births of infants with different malformations was studied with all three statistical methods χ^2 for heterogeneity between months Edwards method and the squared sinus function This was done on the uncorrected material and on the material corrected for the monthly fluctuation of normal births as recorded in an earlier paper (7) and shown in Table 3 The χ^2 values for heterogeneity in the column for corrected values in Table 4 is thus performed with the found number each month and the expected number that month presuming a constant incidence throughout the year (for January the expected number of a malformation with a total number of N will be 0 0820 N)

When Edwards method is used the found number a certain month was increased with a factor compensating for the uneven distribution of normal births (for January this factor will be 8 33/8 20=1 02)

Statistically significant results were obtained for anencephaly only

Anencephaly shows a probably significant variation in the distribution according to the χ^2-test for both uncorrected and corrected values, a seasonality can be detected also with Edwards method, but only for corrected values whereas the squared sinus method gives no support for a rhythmic seasonality

Fig 1 A shows the actual distribution of births at anencephaly and the deviations ($2[\sqrt{F}-\sqrt{E}]$) used for graph fitting

Either *spina bifida aperta* or *hydrocephalus* show any seasonality according to month of birth

II *Seasonality according to LMP*

It is possible that a seasonality can exist for a malformation when it is referred to the time of

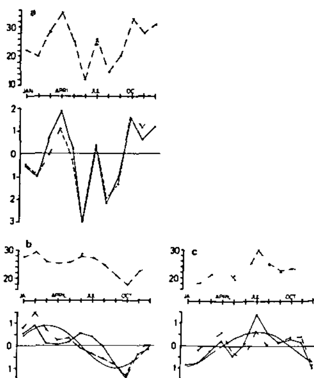

Fig 1 Monthly distribution of births (MB) and month of LMP of malformed infants Upper graph shows actual numbers of malformed infants born each month (dots and dashes) and expected numbers (dots) at a constant malformation rate but with consideration given to monthly variations in total birth rate Lower graph shows recorded deviations between found and expected numbers transformed to normality by the $2\sqrt{N}$ method Whole line is not corrected but dashed line is corrected for monthly variations in total birth rate Squared sinus functions are shown when significant (*a*) Anencephaly (MB) (*b*) anencephaly (LMP) (*c*) spina bifida aperta (LMP)

conception but that the seasonality becomes hidden by marked differences in gestational length for infants with the malformation In order to investigate this possibility the monthly distribution of LMP was studied instead The gestational length was not known for most infants as the date of LMP is not reported to the Register of Congenital Malformations The LMP distribution was therefore calculated as follows

For normal infants the pregnancy length was known for a sample consisting of 5606 infants (Table 3 cf Sandahl 7) From those values the distribution according to month of LMP for normal infants could be estimated For infants with CNS malformation samples with known gestational length were used to estimate the distribution according to LMP of the material from the Register of Congenital Malformations These samples were ascertained from records from Malmo and Lund hospitals and from the ' In patient statistics from the hospitals in the Uppsala region Table 5 shows the distribution of these births according to gestational age From these data the monthly distribution according to LMP was extrapolated for the material from the Register of Congenital Malformations This presupposes that the samples used for estimating pregnancy length and that contained in the Register of Congenital Malformations do not differ with respect to gestational length distribution which appears to be a reasonable supposition

Table 4 gives the values for χ^2 tests for heterogeneity χ^2 at Edwards model and F

Table 5 *Distribution of gestational age in weeks*

For normal infants each age class is given as % of all such births with its error For each type of malformation the actually found numbers (F) and those expected from the normal material (E) are given

values for the squared sinus function with and without correction for the monthly LMP distribution of normal births

Anencephaly gives no significant χ for heterogeneity and the χ^2 values do not quite reach statistical significance when Edwards formula is applied The squared sinus function however is now significant at uncorrected data and strongly significant when corrections for the normal LMP distribution are performed

Fig 1B shows the LMP distribution for this malformation

Spina bifida aperta shows a probable significance only for the squared sinus function and uncorrected data (Fig 1C) Finally *hydrocephalus* shows no significance with either χ^2 for heterogeneity Edwards model or squared sinus function

DISCUSSION

Seasonal variations of specific malformation rates have been much debated and different studies have recorded variable findings This is illustrated by Table 1 which summarizes the literature on anencephaly This table also shows that the mode of analysis has varied considerably In some studies for instance a correction was made for monthly variations in total birth rates in others not In some studies considerations have been given to differences in pregnancy length between malformed and normal infants especially in studies of anencephaly, in others not We have therefore studied the distributions recorded both concerning month of birth and month of LMP we have also studied them with and without corrections for monthly changes in birth rates We think that it cannot *a priori* be stated which mode of analysis is best as they can mirror different causes of seasonality

If factors acting in connexion with conception or at a certain relatively constant time thereafter—which should be the condition when seasonality is due to an exogenous teratogen acting at a specific stage of organogenesis—obviously the LMP month is the adequate variate to study If such a seasonality exists it will be apparent also at the time of birth provided that the gestational length of infants with the malformation involved does not deviate markedly from that of normal infants Should there be a marked deviation a distribution apparent when referred to LMP can be hidden at term if the studied material is limited An example of that was found in anencephaly at term no real seasonality could be discerned but it appeared when the study was performed on LMP dates instead If the malformed infants have normal or near normal

gestational length nothing is gained by referring the distribution to LMP Factors acting near term can be imagined as a cause of seasonality in which case the distribution at term would be less blurred than the LMP distribution A truly teratogenic factor acting at this time is in most cases improbable but factors causing for instance brain damage could be relevant Another and perhaps more important factor which would be tied to the month of birth is one that would affect the efficiency in registration of the individuals One such factor could be holiday times with less experienced or more conscientious personnel observing and reporting the infants another would be a factor that would cause a shift of pregnancy length thus for instance placing anencephalic premature infants into the category of late abortions and thereby changing the reported incidences resulting in an apparent seasonality

Corrections for monthly distribution of normal births give a more correct picture when the seasonality of a factor is studied which can hit any pregnancy with approximately the same probability This for instance is reasonably the case with a purely genetically determined malformation with full penetrance The causal factor in this case shows no seasonality but the rhythm of normal births would cause a seasonality were no correction made for it On the other hand the correction for the monthly normal birth variations can cause a false seasonality if applied on a malformation that can only—or mainly—appear in infants to a certain category of women who are excluded from the normal birth rhythms This could for instance apply to women of a certain age Such considerations must be taken into account when biological conclusions are drawn from the recorded data

Anencephaly

As Figs 1A and 1B show a seasonality does exist for anencephaly in Sweden and it is most obvious and reaches the highest statistical significance when analysed with respect to LMP distribution and with corrections for montly fluctuations in normal births

It is reasonably explained by a teratogenic *factor of one or other sort* acting during early pregnancy As anencephalic infants show a shorter and more variable gestational length than do normal infants the clearcut seasonal pattern observed for LMP will be blurred when studied at term

The seasonal rhythm of anencephalic births resembles that seen for stillbirths (7) Anencephaly contributes to only a small fraction of the total number of stillbirths and the seasonality of anencephaly cannot cause the seasonality of stillbirths in general although both phenomena could be the expression of one and the same basic phenomenon

Spina bifida aperta

The seasonal rhythm of spina bifida aperta is less conspicuous than that of anencephaly (cf Figs 1B and 1C) but a probably significant peak exists with LMP in July This is four months later than that found for anencephaly To ensure that the two recorded patterns are not random variations of one and the same pattern a variance analysis was performed as detailed in Table 6 The variance ratio F_1 in this Table shows that the two malformation groups differ significantly When this is broken up into effect of month of origin of sinus function and effect of coefficients α and β both *factors are shown to be* significant Spina bifida aperta thus has a seasonality different from anencephaly The actual graph for corrected values for spina bifida aperta (Fig 1C) suggests that two peaks exist a spring peak resembling that seen with anencephaly and an autumn peak In the uncorrected data a July peak dominates

General comments

Two malformations of the central nervous system show a seasonal pattern with an identifiable rhythm anencephaly and spina bifida aperta Peak incidences for LMP were found

Table 6 *Variance analysis comparing the squared sinus functions estimating LMP incidence of anencephaly and spina bifida aperta after correction for monthly birth rate fluctuations*

values for the squared sinus function with and without correction for the monthly LMP distribution of normal births

Anencephaly gives no significant χ^2 for heterogeneity and the χ^2 values do not quite reach statistical significance when Edwards formula is applied *The squared sinus function however is now significant at uncorrected data and strongly significant when corrections for the normal LMP distribution are performed*

Fig 1 B shows the LMP distribution for this malformation

Spina bifida aperta shows a probable significance only for the squared sinus function and uncorrected data (Fig 1 C) Finally *hydrocephalus* shows no significance with either χ for heterogeneity Edwards model or squared sinus function

DISCUSSION

Seasonal variations of specific malformation rates have been much debated and different studies have recorded variable findings This is illustrated by Table 1 which summarizes the literature on anencephaly This table also shows that the mode of analysis has varied considerably In some studies for instance a correction was made for monthly variations in total birth rates in others not In some studies considerations have been given to differences in pregnancy length between malformed and normal infants especially in studies of anencephaly in others not We have therefore studied the distributions recorded both concerning month of birth and month of LMP we have also studied them with and without corrections for monthly changes in birth rates We think that it cannot *a priori* be stated which mode of analysis is best as they can mirror different causes of seasonality

If factors acting in connexion with conception or at a certain relatively constant time thereafter—which should be the condition when seasonality is due to an exogenous teratogen acting at a specific stage of organogenesis—obviously the LMP month is the adequate variate to study If such a seasonality exists it will be apparent also at the time of birth provided that the gestational length of infants with the malformation involved does not deviate markedly from that of normal infants Should there be a marked deviation a distribution apparent when referred to LMP can be hidden at term if the studied material is limited An example of that was found in anencephaly at term no real seasonality could be discerned but it appeared when the study was performed on LMP dates instead If the malformed infants have normal or near normal

CHRONIC ACTIVE HEPATITIS IN CHILDREN

A Clinical and Immunological Long term Study

K LIDMAN G BIBERFELD G STERNER and R NORBERG

From the Department of Infectious Diseases Danderyd hospital Danderyd Department of Immunology National Bacteriological Laboratory Stockholm and the Stockholm County Council Central Microbiological Laboratory Stockholm Sweden

ABSTRACT Lidman K Biberfeld G Sterner G and Norberg R (Department of Infectious Diseases Danderyd Hospital Danderyd Department of Immunology National Bacteriological Laboratory Stockholm and the Stockholm County Council Central Microbiological Laboratory Stockholm Sweden) Chronic active hepatitis in children a clinical and immunological long term study Acta Paediatr Scand 66 73 1977.—Six girls and one boy with chronic active hepatitis (CAH) of unknown etiology were between 9 and 15 years at the clinical onset of their illness After beginning immunosuppressive therapy the course of their disease was followed from one to ten years All had markedly increased IgG high titres of smooth muscle antibodies (SMA) and antinuclear antibodies of IgG class in the earliest serum specimens tested Therapy resulted in an improved sense of well-being and a decrease in SGOT IgG and titres of SMA Very high titres of measles antibodies were observed in all cases In one of the cases CAH manifested itself after measles and in another after rubella infection The first case in our series of patients died of liver failure after 5 years of illness The other patients have survived and are able to live a normal life The possibility of CAH should be considered when children develop symptoms of hepatitis Long term immunosuppressive treatment with regular clinical and laboratory evaluation is important Estimation of titres of SMA is an additional parameter of value in *following of the* activity of CAH in these young patients

KEY WORDS Chronic active hepatitis follow up smooth muscle antibodies measles antibodies

Chronic active hepatitis (CAH) is a clinical entity characterized by a chronic progressive liver disease with superimposed episodes of activity (37) The characteristic histological appearance is that of chronic aggressive hepatitis (6) The etiology is only partly recognized It can be associated with hepatitis B infection (24) or with the use of drugs e g laxatives containing oxyphenisatin (29) But there is also a group of patients usually females with marked changes in immunological reactivity where the cause is unknown These patients often have antinuclear antibodies (ANA) (2) smooth muscle antibodies (SMA) (15) and high titres of antibodies to measles and rubella (4 16 35) All age groups may be affected by CAH but in approximately fifty per cent of the cases of unknown etiology the onset occurs between the ages of ten and thirty years (22) The response to treatment with immunosuppressive drugs is usually favourable and survival is prolonged (5 23 31)

The aim of the present study was to follow the clinical course liver function tests immunoglobulins autoantibodies and antibodies to measles and rubella in young patients with CAH on immunosuppressive therapy

MATERIAL AND METHODS

The patients studied 6 girls and 1 boy were between 9 and 15 years with an average age of 12 at the onset of illness The *mean observation* time was 5 5 years with a range of 1 5 to 10 years *All patients* were hospitalized several times and also monitored as *outpatients* every

during spring months (Febr –April) at anencephaly Spina bifida showed the most obvious peak when data not corrected for birth rate fluctuations were used A July peak was then seen For corrected data, a spring peak (April) and an autumn peak (September) are indicated The differences in peak months suggest that the described rhythms are not artefactual but are due to actual variations in malformation risk during different parts of the year Whether this is due to endogenous factors relating to fertility for instance or whether it is due to a seasonality in teratogenic factors cannot be decided

before she developed jaundice Case 7 had rubella six months before the onset of jaundice and since that infection she had persistent malaise and fatigue

There was a considerable increase in SGOT and serum IgG in the earliest specimens tested (Table 1) Serum IgA and IgM showed no apparent elevation and α_1 antitrypsin was normal HB Ag and anti HB, could not be demonstrated All patients had high titres of ANA and SMA (Table 1) The SMA were of IgG class Needle biopsies of the liver performed in case 1–6 showed lesions consistent with chronic aggressive hepatitis Biopsy had to be postponed in case 7 because of her tendency to bleed easily She also had signs of hemolytic anemia with Coombs direct and indirect tests positive Multisystem involvement was not seen in the other cases

When the diagnosis of CAH was established therapy was introduced In case 1 (Table 1) steroids were given for only short periods in the first three years This improved her sense of well being but did not control the progressive liver damage In 1967 azathioprine was added to her therapy with minimal effect The drug had to be withdrawn when the patient developed leucopenia and a Staphylococcus aureus septicaemia The infection was successfully treated but the liver function deteriorated rapidly and she bled from oesophageal varices Despite a splenorenal shunt bleeding recurred and the patient died in 1968 At necropsy the liver was moderately decreased in size with signs of severe postnecrotic cirrhosis and intense infiltration with monocytes and lymphocytes The spleen removed at the shunt operation was hypertrophic (860 g) with an abundance of plasma cells in the red pulp

Case 2–7 have received continuous immunosuppressive treatment for long periods (Table 1) This therapy has resulted in good symptomatic relief and the patients have been able to attend school or to work most of the time There was a good correlation between the decrease in levels of transaminases and the decrease in IgG and titres of ANA and SMA although the decrease in transaminases was more rapid (Table 1) Case 2 has been treated for 10 years Her disease has shown activity as measured by SGOT IgG and SMA on several occasions The galactose tolerance and bromsulphalein retention test were normal in 1972 However in 1975 the liver function was impaired and the disease showed increasing signs of activity despite therapy In case 3 therapy was discontinued after 5 years and she has remained in remission for 2 years In cases 4–7 the disease has been controlled and relapses have not occurred Bromsulphalein retention and galactose tolerance tests are normal in cases 3 4 6 and 7 and slightly abnormal in case 5 Successful liver biopsies have been performed during therapy in cases 3 and 6 These showed regression of the pathological changes to an almost normal histo

				1975 (Dec)	0 6	39	12 9	<10	25

The disease in case 1 diagnosed 1963 Treated by us from 1967
[b] Case 6 developed jaundice in 1971 after measles infection This disappeared spontaneously before admittance to hospital

second or third month at the Department of Infectious diseases Danderyd hospital Blood samples taken on these occasions were centrifuged and stored at −20 C

Bilirubin (normal value 0 2–1 2 mg/100 ml or 4–21 μmol/l) and serum glutamic oxaloacetic transaminase (SGOT) (normal value 10–35 Karmen μ/ml or 0 08–0 28 μmols s⁻¹/l) were *regularly estimated Galactose* toler ance test (34) and bromsulphalein retention test (30) were performed The amount of α_1 antitrypsin was measured by agarose electrophoresis (14) The concentrations of immunoglobulins were estimated by single radial immuno-diffusion (20) (normal values IgG 11 ?±2 g/l IgA 1 9± 0 7 g/l IgM 0 7±0 2 g/l) Serum specimens were tested in a radioimmunoassay (AusRIA II and AusAb Abbot Laboratories Chicago Illinois *USA) for the presence of* hepatitis B surface antigen (HB_sAg) and hepatitis B sur face antibody (anti HB_s) Autoantibodies (ANA SMA) were demonstrated by indirect immunofluorescence (IFL) (17) Titres of rubella HI (32) and measles HI (25) and HLI antibodies (25) were also determined Liver biopsies were obtained by the Menghini technique (21) The histological changes were classified according to Alpert et al (1) and de Groote et al (6)

The clinical diagnosis of CAH was based on the finding of lesions consistent with chronic aggressive hepatitis on examination of the liver biopsies together with the pres ence of increased serum bilirubin prolonged elevation of transaminases considerably elevated IgG values and titres of ANA and SMA

All patients received immunosuppressive treatment Drugs used in the individual patients are shown in Table 1 In cases 2–7 the initial dose of Prednisolone given during the first week was 0 75–1 mg/kg/day This dose was then gradually reduced during a few weeks time to a mainte nance dose of 0 15–0 25 mg/kg/day (or in case 4 triam cinolone 0 04 mg/kg/day) Azathioprine when used was given in a dose of 1–2 mg/kg/day not exceeding 100 mg as a total daily dose

RESULTS

Before the onset of CAH the patients had been healthy except for asthma in early childhood in case 1 None had any known contact with viral hepatitis of type A or B or with drugs that could cause liver damage In case 1–5 the on set of disease was acute *with nausea fatigue* and jaundice Case 6 had measles one month

Treatment
1963–67 short periods with steroids *a* 1967 aza 1968 triamcinolon
1966–67 pred + aza 1967 70 aza 1970– pred + aza
1968 pred + aza
1973 no therapy
1969 pred + aza 1970– triamcinolon + aza
1970–75 pred + aza (June) 1975– no therapy
197?–75 pred + aza (Feb)
1973– pred
1974– pred + aza

before she developed jaundice Case 7 had rubella six months before the onset of jaundice and since that infection she had persistent malaise and fatigue

There was a considerable increase in SGOT and serum IgG in the earliest specimens tested (Table 1) Serum IgA and IgM showed no apparent elevation and α_1 antitrypsin was normal HB Ag and anti HB could not be demonstrated All patients had high titres of ANA and SMA (Table 1) The SMA were of IgG class Needle biopsies of the liver performed in case 1–6 showed lesions consistent with chronic aggressive hepatitis Biopsy had to be postponed in case 7 because of her tendency to bleed easily She also had signs of hemolytic anemia with Coombs direct and indirect tests positive Multisystem involvement was not seen in the other cases

When the diagnosis of CAH was established therapy was introduced In case 1 (Table 1) steroids were given for only short periods in the first three years This improved her sense of well being but did not control the progressive liver damage In 1967 azathioprine was added to her therapy with minimal effect The drug had to be withdrawn when the patient developed leucopenia and a Staphylococcus aureus septicaemia The infection was successfully treated but the liver function deteriorated rapidly and she bled from oesophageal varices Despite a splenorenal shunt bleeding recurred and the patient died in 1968 At necropsy the liver was moderately decreased in size with signs of severe postnecrotic cirrhosis and intense infiltration with monocytes and lymphocytes The spleen removed at the shunt operation was hypertrophic (860 g) with an abundance of plasma cells in the red pulp

Case 2–7 have received continuous immunosuppressive treatment for long periods (Table 1) This therapy has resulted in good symptomatic relief and the patients have been able to attend school or to work most of the time There was a good correlation between the decrease in levels of transaminases and the decrease in IgG and titres of ANA and SMA although the decrease in transaminases was more rapid (Table 1) Case 2 has been treated for 10 years Her disease has shown activity as measured by SGOT IgG and SMA on several occasions The galactose tolerance and bromsulphalein retention test were normal in 1972 However in 1975 the liver function was impaired and the disease showed increasing signs of activity despite therapy In case 3 therapy was discontinued after 5 years and she has remained in remission for 2 years In cases 4–7 the disease has been controlled and relapses have not occurred Bromsulphalein retention and galactose tolerance tests are normal in cases 3 4 6 and 7 and slightly abnormal in case 5 Successful liver biopsies have been performed during therapy in cases 3 and 6 These showed regression of the pathological changes to an almost normal histo

logical pattern In cases 5 and 7 biopsy material was inadequate The hemolytic anemia was controlled in case 7 and her tendency to bleed has disappeared All patients showed very high titres of measles antibodies (Table 2) Case 7 in which the disease manifested itself after rubella infection also had high titres of rubella antibodies

DISCUSSION

The onset of CAH in children is often clinically difficult to distinguish from acute hepatitis (8) Five of seven patients had an acute onset of disease Six patients had SGOT values of approximately 1 000 when first examined which is a common finding in acute hepatitis However, the disease in the patients studied was diagnosed as CAH because of the prolonged course marked elevation of IgG values occurrence of high titres of ANA and SMA of IgG class and lesions consistent with chronic aggressive hepatitis in the liver biopsies carried out in six of the seven patients

Multisystem involvement is common in adults with CAH (12) but this was not seen among these young patients except for the occurrence of hemolytic anemia in case 7 This condition has been described previously as an unusual concomitant to CAH (26)

The IgG values were markedly elevated at the onset of the disease and decreased during immunosuppressive therapy One explanation for the hypergammaglobulinaemia in CAH and other chronic liver diseases is failure of the Kupffer cells in the diseased liver to trap antigens particularly microbial antigens from the gut resulting in increased antigen stimulation and increased antibody production (for review

see (3)) In CAH the increased antibody production may also be due to a genetically determined defect in immunoregulation It has been shown that increased titres of antibodies to measles rubella smooth muscle and nuclear antigens in patients with CAH are associated with the presence of histocompability antigens B 8 and B 12 (11) It is of interest that two cases in the present study had a viral infection shortly before onset of liver symptoms (case 6 measles and case 7 rubella) Two of the other cases had had measles the year before the onset of disease We have also observed another child (not treated at Danderyds hospital) who developed symptoms of CAH one month after measles infection (unpublished) This could suggest that these viral infections also might be of pathogenetic importance

Sera with SMA titres greater than 80 are usually derived from patients with CAH (7 13 18) In the present cases of CAH the titres of SMA were above this level at the clinical onset of the disease SMA occurring in CAH are directed against the contractile protein actin (10 18) which is present in the cytoplasm of both muscular and nonmuscular cells It is considered that during the disease process actin in the liver cells in some unknown way is made immunogenic and the production of antiactin antibodies is stimulated These antibodies do not react with the surface of normal living cells (9) and there is at present no evidence that they are cytotoxic to liver cells (28) Therefore the importance of these autoantibodies is considered primarily to be diagnostic (7)

Murray Lyon et al (23) in their controlled trial of treatment in adult patients with CAH found no apparent relationship between changes in titres of auto-antibodies including SMA and alterations in liver function tests Whittingham et al (36) however reported that SMA disappeared in 4 cases after a long remission Our experience in the present young patients is that the titre of SMA correlated well with the activity of the disease and that SMA can disappear after a long remission of the disease Therefore SMA can be an additional parameter of value in the follow up of patients

Three controlled studies mainly of adults with CAH observed for 2–5 years showed that immunosuppressive therapy reduced the activity of the disease and increased the survival (5 23 31) Dubois et al (8) in an uncontrolled study of 28 children with CAH (average age at onset 9 years and 8 months) found that the initial response to corticosteroid therapy was excellent in all but 3 patients In order to reduce side effect of corticosteroids he recommended as maintenance therapy azathioprine (1 mg/kg/day) in combination with a small dose of prednisolone

No definite conclusions about therapy can be drawn from our small series of patients However some comments can be made In case 1 the therapy did not prevent the progress of the disease This case also illustrates the risk that azathioprine may cause leucopenia White blood count must be regularly monitored when this drug is given In cases 2–7 the therapy has permitted the patients to live a normal life Case 2 has survived for ten years but her disease is now active despite therapy The other five cases are in remission three of them with therapy and two after withdrawal of therapy

The best therapeutic regime known at present is a combination of azathioprine (1–1 5 mg/kg) and prednisolone in the smallest dose which still controls the disease process The main advantage of the combination therapy is the possibility to reduce the maintenance dose and thereby the side effects of prednisolone (33) It is not known when treatment should be stopped Mackay (19) however states that it is reasonable to try to discontinue therapy when the activity of the disease remains controlled after two to three years of treatment Then there is a sustained remission in about 25% of the CAH patients 50% will require new courses of therapy and in 25% the disease seems to progress despite therapy

THE EFFECT OF L DOPA WITH AND WITHOUT DECARBOXYLASE INHIBITOR ON GROWTH HORMONE SECRETION IN CHILDREN WITH SHORT STATURE

F Ø FEVANG K F STØA T THORSEN and D AARSKOG

From the Department of Paediatrics and the Hormone Laboratory University of Bergen Bergen Norway

ABSTRACT Fevang F Ø Støa K F Thorsen T and Aarskog D (Department of Paediatrics and the Hormone Laboratory University of Bergen Bergen Norway) The effect of L-dopa with and without decarboxylase inhibitor on growth hormone secretion in children with short stature Acta Paediatr Scand 66 81 1977.—The efficiency of L-dopa alone and L-dopa plus a dopa-decarboxylase inhibitor (carbidopa) in provoking growth hormone (GH) secretion was studied in 40 children with short stature By preventing the extracerebral metabolism carbidopa increases the availability of L-dopa to the brain The study was designed as paired series of growth hormone stimulation tests in which the effect of L-dopa alone in different dosage schedules was compared with the same dose level of L-dopa plus carbidopa When L-dopa was given in full dose (125–500 mg) there was no significant difference in the serum GH concentrations at any time of sampling In the lower dose level the stimulant effect of L-dopa alone tended to be exceeded by the combination of L-dopa and carbidopa The serum GH responses to the different schedules indicate that an optimal hypothalamic dopamine concentration for GH release could be achieved with a considerably lower dose of L-dopa than those employed in previously reported studies When L-dopa is combined with a dopa decarboxylase inhibitor the children have the advantage of less side effects in the form of nausea and vomiting

KEY WORDS L-dopa dopa-decarboxylase inhibitor growth hormone

Dopaminergic mechanisms play a major role in hypothalamic function and are important regulators of growth hormone (GH) secretion Several studies have shown that oral L-dopa causes a significant rise in serum GH concentration and the drug has been found useful as a provocative agent in the GH stimulation test However in all studies there has been a certain number of non responders varying from 10 to 20 % of non hypopituitary subjects (6)

L dopa crosses the blood brain barrier and is converted to dopamine which functions as a neurotransmitter and mediates the secretion of GH releasing factor through activation of dopaminergic receptors The enzyme dopa decarboxylase catalyses the conversion of L dopa to dopamine both inside and outside the brain Some 95 % of an oral dose of L-dopa is decarboxylated outside the brain parenchyme in the gut wall liver kidney and other organs so that only a very small fraction actually reaches the dopaminergic receptors in the hypothalamus (2 4) The dopa decarboxylase inhibitor carbidopa inhibits peripheral utilization of L dopa and should increase the amount of L dopa available to the brain and thus possibly augment the GH response The purpose of this study was to test this hypothesis by comparing the efficiency of L dopa alone and L-dopa plus carbidopa in provoking GH secretion in children with short stature

SUBJECTS AND METHODS

The material consists of 40 children admitted to the Children s Hospital in Bergen for evaluation of short stature The purpose and nature of the study were care

time of sampling In this series there was one non responder to the reduced dose of L-dopa with carbidopa whereas all children responded to the full dose of L dopa

In the third series of 9 children who received a reduced dose of both agents there was one non responder to each test Although not significantly different both the mean GH concentration at 60 min and the mean peak concentration were higher following L dopa plus carbidopa than after L dopa alone 10 1 ng/ml versus 6 4 ng/ml ($p>0$ 40) and 14 7 ng/ml versus 9 8 ng/ml ($p>0$ 30) respectively

In Fig 1 the data from all 3 test series have been compiled according to type of drug and dose schedule L dopa alone was tested in full dose in 31 children and in reduced dose in 9 whereas L-dopa with carbidopa in reduced dose was tested in 17 children altogether The only prominent difference between the curves was a somewhat lower mean GH concentration at 60 min following the reduced dose of L-dopa 6 4±1 5 ng/ml compared to 9 6±1 3 ng/ml following full dose of L-dopa and 10 5±2 2 ng/ml following reduced dose of L-dopa plus carbidopa However the differences between these means were not significant (0 10 $<p<0$ 20) The mean peak GH concentration was 9 8±1 7 ng/ml after reduced dose of L dopa alone which was not significantly different from the mean peak response of 12 5±1 3 ng/ml (0 30$<p<0$ 20) following full dose or to the peak response of 14 6±2 1 ng/ml ($p=0$ 10) to the reduced dose of L dopa plus carbidopa

Among the 31 children who received a full dose of L-dopa there was a total of 3 non responders (10%) and an additional 3 showed a subnormal response with a peak GH concentration between 5 and 7 ng/ml Two of the 17 children receiving reduced dose of L-dopa plus carbidopa failed to respond (11 5%) and 3 showed a subnormal response

Some of the children experienced nausea and occasionally emesis during the test This unpleasant side effect occurred both when L dopa was given alone and in combination with

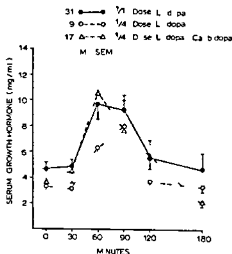

Fig 1 Serum growth hormone response to L-dopa at different dose levels and to L dopa combined with carbidopa

carbidopa However both nausea and vomiting were less frequent when the children were tested with the reduced dose of L dopa with carbidopa

DISCUSSION

A number of methods have been designed to evaluate pituitary deficiency as assessed by release of GH in response to different stimuli (6) In 1970 Boyd and co-workers reported that L dopa stimulated GH release in patients with Parkinson s disease (3) and subsequently several studies have proved the efficacy of L dopa as a reliable provocative agent for GH release in children (5 9–12) In these studies 80 to 90% of children who are not deficient in GH have responded to this stimulant These observations are confirmed and extended by our results In their original study of adult patients with Parkinson s disease Boyd and co-workers used a test dose of 500 mg of L dopa In studies involving children this test dose has either been adopted unchanged (11) or modified according to body surface area (12) or body weight (5 9 12) The basis of the different dose schedules used in the present study which was a mg per lb to mg

Table 1 *Comparison of growth hormone response (ng/ml) to L dopa and L dopa plus carbidopa* Means±S E M

Drug	Dose	No of children	Minutes 0	30	60	90	120	180	Peak

1/1 dose 125 mg L dopa to children <15 kg 250 mg to children 15–35 kg 500 mg to children >35 kg

fully explained to the parents and their consent was obtained There were 8 girls and 32 boys whose ages ranged from 3 to 15 years With one exception all had heights below the 2 5 percentile On the basis of history clinical examination bone age X rays and endocrine studies all were considered to have non endocrine causes for their short stature

The study was designed as paired series of growth hormone stimulation tests in which the effect of L dopa alone (Larodopa® Roche) on GH release was compared with that of a combination of L dopa and the dopadecarboxylase inhibitor carbidopa (Sinemet® MSD 25 mg carbidopa per 250 mg L dopa) After an overnight fast of 8 to 12 hours an indwelling cannula was inserted into an antecubital vein and kept open with heparinized saline Following 30-min rest a single dose of the test drug was administered by mouth and blood samples were subsequently obtained after zero 30 60 90 120 and 180 min respectively for the determination of serum GH The test dose of L-dopa was based on the weights of the children Those who weighed less than 15 kg received 125 mg those 15 to 35 kg received 250 mg those above 35 kg 500 mg The tests were separated by intervals of 24 hours and alternated so that every other child had the L dopa with carbidopa test first Twenty three of the children were tested with both drugs in full dose In a second series which included 8 children the effect of the full dose of L dopa alone was compared with one fourth dose of L dopa combined with carbidopa Finally the effect of one fourth dose of both drugs was compared in another series of 9 children

The serum GH was determined by a radioimmunosorbent method (13) The HGH preparation used as standard was obtained from Calbiochem A G Switzerland and contained 2 2 I U HGH per mg

RESULTS

The mean (±S E M) serum GH concentration at each time interval together with the mean peak concentration irrespective of time are shown in Table 1 When used in full dose the response to L dopa alone and L dopa with carbidopa were fairly similar The maximum response to L dopa alone occurred at 60 min with a mean GH concentration of 9 9 ng/ml and at 90 min with a mean of 11 7 ng/ml following L dopa with carbidopa The mean GH concentration at 60 and 90 min were significantly above the zero time value following L dopa and at 60 90 and 120 min after L dopa plus carbidopa (0 001<p<0 01) The mean peak GH concentration irrespective of time was 12 5 ng/ml after L dopa and 15 5 after L dopa with carbidopa There was no significant difference between these mean values or those at any individual time of sampling When a peak GH concentration of 5 ng/ml or more was arbitrarily considered to indicate a normal response there were two non responders to L dopa alone whereas one did not respond to the combination of L dopa and carbidopa One child who did not respond to either drug subsequently showed a normal response to an insulin provocation test

In the series of 8 children tested with the full dose of L dopa and a quarter dose of L dopa plus carbidopa the maximum response to both agents occurred at 60 min with a mean GH concentration of 9 1 ng/ml respectively 11 0 ng/ml There was no significant difference between these mean values or those at any other

time of sampling In this series there was one non responder to the reduced dose of L-dopa with carbidopa whereas all children responded to the full dose of L dopa

In the third series of 9 children who re ceived a reduced dose of both agents there was one non responder to each test Although not significantly different both the mean GH concentration at 60 min and the mean peak concentration were higher following L dopa plus carbidopa than after L dopa alone 10 1 ng/ml versus 6 4 ng/ml ($p>0$ 40) and 14 7 ng/ml versus 9 8 ng/ml ($p>0$ 30) respectively

In Fig 1 the data from all 3 test series have been compiled according to type of drug and dose schedule L dopa alone was tested in full dose in 31 children and in reduced dose in 9 whereas L dopa with carbidopa in reduced dose was tested in 17 children altogether The only prominent difference between the curves was a somewhat lower mean GH concentra tion at 60 min following the reduced dose of L-dopa 6 4±1 5 ng/ml compared to 9 6±1 3 ng/ml following full dose of L dopa and 10 5± ?? ng/ml following reduced dose of L dopa plus carbidopa However the differences be tween these means were not significant (0 10 $<p<0$ 20) The mean peak GH concentration was 9 8±1 7 ng/ml after reduced dose of L dopa alone which was not significantly dif ferent from the mean peak response of 12 5± 1 3 ng/ml (0 $30<p<0$ 20) following full dose or to the peak *response of* 14 6±2 1 ng/ml ($p=0$ 10) to the reduced dose of L dopa plus carbidopa

Among the 31 children who received a full dose of L dopa there was a total of 3 non responders (10%) and an additional 3 showed a subnormal response with a *peak GH* con centration between 5 and 7 ng/ml Two of the 17 children receiving reduced dose of L dopa plus carbidopa failed to respond (11 5%) and 3 showed a subnormal response

Some of the children experienced nausea and occasionally emesis during the test This unpleasant side effect occurred both when L dopa was given alone and in combination with

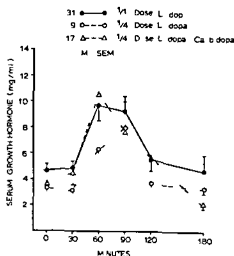

Fig 1 Serum growth hormone response to L-dopa at different dose levels and to L dopa combined with carbi dopa

carbidopa However both nausea and vomit ing were less frequent when the children were tested with the reduced dose of L dopa with carbidopa

DISCUSSION

A number of methods have been designed to evaluate pituitary deficiency as assessed by release of GH in response to different stimuli (6) In 1970 Boyd and co-workers reported that L dopa stimulated GH release in patients with Parkinson s disease (3) and subsequent ly several studies have proved the efficacy of L dopa as a reliable provocative agent for GH release in children (5 9–12) In these stud ies 80 to 90% of children who are not defi cient in GH have responded to this stimulant These observations are confirmed and ex tended by our results In their original study of adult patients with Parkinson s disease Boyd and co-workers used a test dose of 500 mg of L dopa In studies involving children *this test* dose has either been adopted un changed (11) or modified according to body surface area (12) or body weight (5 9 12) The basis of the different dose schedules used in the present study which was a mg per lb to mg

per kg conversion of the 125 to 500 mg dose proposed by Weldon and co workers (12) represents a dose in the lower range of those used in the different studies in children

Animal experiments have indicated that only a small fraction of orally administered L dopa enters the brain and that this portion is significantly increased by the concurrent use of systemic decarboxylase inhibitors (1) These experimental results are in accordance with clinical experience in patients with Parkinson s disease where the dose of L dopa required for optimum therapeutic benefit can be reduced when L dopa is combined with carbidopa (8)

When used in the highest dose level L dopa with carbidopa did not augment the GH release above that obtained with L dopa alone This finding might infer that the hypothalamic dopaminergic receptors involved in the modulation of GH releasing factors react to a threshold concentration of dopamine or to concentrations up to a certain limit and that further increase in the dopamine level will not enhance the stimulus In the lower dose level employed in the present study stimulant effect of L dopa alone tended to be exceeded by L dopa combined with carbidopa The responses to the different schedules indicate that an optimal hypothalamic dopamine concentration for GH release could be achieved with a considerably reduced dose of L dopa when combined with a dopa decarboxylase inhibitor (Fig 1)

The children who received the reduced dose of L dopa plus carbidopa had the advantage of less nausea and vomiting than those tested with full dose of L dopa alone Nausea and vomiting are probably due to the effect of dopa metabolites on the medullary emetic zone, possibly the area postrema which lies outside the blood brain barrier for dopamine (7) The reduction of these side effects could probably be due to carbidopa blocking the formation of dopamine in extracerebral tissue thus decreasing the degree of dopaminergic stimulation of the medullary emetic zone

LOW MOLECULAR WEIGHT ORGANIC ACIDS IN THE URINE OF THE NEWBORN

N GREGERSEN J INGERSLEV and K RASMUSSEN

From the Biochemical Research Unit University Department of Clinical Chemistry and the University Department of Obstetrics and Gynaecology Århus Kommunehospital Århus Denmark

ABSTRACT Gregersen N Ingerslev J and Rasmussen K (Biochemical Research Unit University Department of Clinical Chemistry and University Department of Obstetrics and Gynaecology Århus Kommunehospital Århus Denmark) Low molecular weight organic acids in the urine of the newborn Acta Paediatr Scand 66 85 1977 —The urinary excretion of seven selected low molecular weight organic acids in normal neonates was measured by gas chromatography First and third to fourth day of life excretion of the following compounds was significantly unchanged 3-OH butyric acid (<13 μmol/mmol creatinine) succinic acid (approx 43 μmol/mmol creatinine) adipic acid (approx 12 μmol/mmol creatinine) 2-OH-glutaric acid (approx 23 μmol/mmol creatinine) 3-OH 3 Me-glutaric acid (approx 25 μmol/mmol creatinine) and citric acid (approx 115 μmol/mmol creatinine) The excretion of 4-OH phenyl-acetic acid increased during the first four days of life (from <8 μmol/mmol creatinine to approx 20 μmol/mmol creatinine) It is postulated that urinary organic acid excretion in the neonate which is clearly different from the adult urinary pattern is a reflection of the specific neonatal metabolic situation including a high fatty acid utilisation and a low protein catabolism

KEY WORDS Low molecular weight organic acids succinic acid adipic acid citric acid neonatal metabolism

Information concerning the normal urinary excretion of low molecular weight organic acids during the first days of human life was until recently very limited Karoum et al (8) investigated the content of phenolic acids in the urine of normal neonates and very recently Bjorkman et al (2) analysed the urinary pattern of organic acids in first day neonates The purpose of the present investigation was to obtain reference values for the concentrations of a selected number of urinary metabolites exceeding approximately 8 μmol/mmol creatinine i e the practical detection limit for precise measurement by the method employed

MATERIAL AND METHODS

Clinical material

Urine was collected from 18 full term neonates (10 males and 8 females) in two periods immediately post partum and on the third to fourth day of life In an additional 10 cases (3 males and 7 females) only a first day portion was obtained

All mothers were healthy on physical examination prior to labour and in no instance signs of preeclampsia were recorded Systemic medications were not given for at least 4 weeks before term In 4 cases a single dose of Menadion (40 mg) was given at onset of labour Two mothers were given pudendal anaesthesia and all received N_2O No other medical treatment was instituted during labour

Duration of labour varied from 1 h 10 min to 8 h 45 min In 26 cases the delivery was by cephalic presentation and in 2 instances by breech

Amniotic fluid and all placentas were normal All infants weighed more than 2 500 g at birth The Apgar score was 10 in all cases 1 min after birth No signs of late asphyxia were recorded and jaundice was not seen Most infants were given minor quantities (?0–40 ml per day) of either glucose (5%) or diluted cow s milk (50%) until lactation was firmly established Weight losses for the first 5 days ranged from 450 g to zero (mean 170 g)

Chemicals

DL 3-OH-butyric acid (Na-salt) succinic acid and 4-OH phenylacetic acid were obtained from Merck A G (Darm

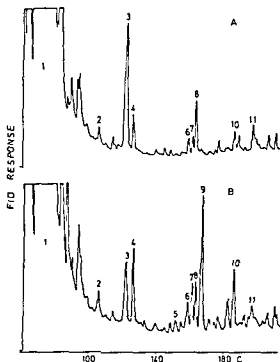

Fig 1 Typical GC profile from neonate girl A first day B third day 1 solvent front 2 3-OH butyric acid 3 urea 4 succinic acid 5 adipic acid 6 2-OH glutaric acid 7 3-OH 3 Me-glutaric acid 8 pimelic acid (int st) 9 4 OH phenylacetic acid 10 citric acid 11 hippuric acid

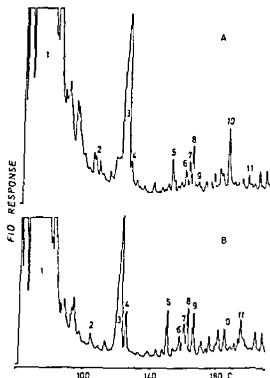

Fig 2 Typical GC profile from neonate boy A first day B third day 1 solvent front 2 3 OH butyric acid 3 urea 4 succinic acid 5 adipic acid 6 2 OH glutaric acid 7 3 OH 3 Me glutaric acid 8 pimelic acid (int st) 9 4-OH phenylacetic acid 10 citric acid 11 hippuric acid

stadt Germany) Adipic acid pimelic acid 2 OH glutaric acid (Zn salt) were obtained from Koch Light Laboratories Ltd (Bucks England) 3 OH 3 Me glutaric acid was purchased from Sigma Chemical Company (St Louis Missouri U S) and citric acid from BDH Chemical Ltd (Poole England) Stationary phase for gas chromatography Dexsil 300 was obtained from Analabs Inc (North Haven Conn U S) and column support chromosorb W (HP) from Koch Light Laboratories Ltd BSTFA and Tri Sil were purchased from Pierce Chemical Co (Rockford Ill U S)

Analytical procedure

Urine samples containing 2 mg (17 5 μmol) creatinine were diluted with equal amounts of saturated NaCl solution and 200 μl of a 400 mg/l (2 5 mmol/l) pimelic acid solution The pH of the mixture was adjusted to 1 with 5 mol/l HCl prior to extraction Three consecutive extractions were made with both ethylether and ethylacetate The organic phases were dried (Na_2SO_4) and the solvent was evaporated in a stream of dry nitrogen The remanence was silylated to TMS ethers/esters at room temperature with Tri Sil (200 μl) and BSTFA (200 μl) 2–8 hours after silylation 4 μl of the mixture was injected into a Hewlett Packard 5830 gas chromatograph The instrument was equipped with a flameionisation detector an integrator and a dedicated computer The column was a 1 8 m×3 mm (i d) glass coil packed with Dexsil 300 (3 %) on Chromosorb W (HP) The temperature of the column was programmed at 4 C/min from 60 C The helium carrier flow rate was 40 ml/min

An aqueous stock solution (50 ml) consisting of 3-OH butyric acid (Na salt 30 mg 265 μmol) succinic acid (25 mg 212 μmol) adipic acid (25 mg 171 μmol) 2 OH glutaric acid (Zn salt 45 mg 212 μmol) 3 OH 3 Me glutaric acid (50 mg 308 μmol) 4 OH phenylacetic acid (25 mg 164 μmol) and citric acid (125 mg 647 μmol) was used as standards in appropriate dilutions

The standards were analyzed according to the procedure described for urines Standard curves of the compounds were straight and through zero The variation coefficients calculated from double determinations on several concentration levels in the standards were 3 OH butyric acid 12% succinic acid 15% adipic acid 9% 2 OH glutaric acid 7% 3 OH 3 Me glutaric acid 7% 4 OH phenylacetic acid 4% and citric acid 8% It was only possible in a few cases to make double determinations on the urine specimens from the children However these analyses indicated that the variation coefficients were in the same order of magnitude as in the standards from 10–15%

The chemical structure as well as the gas chromatographic retention time of the internal standard pimelic acid are so similar to those of the compounds in question that the variation component due to variations in the extraction efficiency are minimal Recovery of the compounds was not quantitative but extraction efficiency was normalised with reference to pimelic acid

Gas chromatography/mass spectrometry

Identification and verification of the detected compounds in urine samples were performed on a AEI MS 30 *double* beam mass spectrometer equipped with a Pye Unicam gas chromatographic inlet system

RESULTS

Typical gas chromatographic profiles of low molecular weight organic acids *from two* neonatal urines are shown in Figs 1 and 2

The profiles are rather complex A *pilot in*vestigation indicated that 3-OH butyric acid succinic acid adipic acid 2-OH glutaric acid 3-OH 3 Me glutaric acid 4 OH phenylacetic acid were identifiable and measurable in al most all pilot urines whereas pimelic acid later used as internal standard was *not de*tected The identification and quantitation of these acids were performed by gas chromatography/computer matching of the unknown profiles to a profile of known amounts of the *acids in question In order to check* the gas chromatographic procedure the identity of the acids in some urine samples was verified in the gas chromatographic/mass spectrometric *system*

The results were allocated to 4 groups 1) *boys first day of life* 2) boys day 3–4 3) girls first day 4) girls day 3–4

The detected concentrations of each acid were not found to be normally distributed within the groups (histogram technique) The nonparametric Wilcoxon tests for two samples (5) showed no significant differences between either groups 1 and 3 or between 2 and 4 The Wilcoxon test of paired differences (5) applied to the excretions on day 1 and day 3–4 matching groups 1+3 to groups 2+4 showed a significantly enhanced excretion of 4 OH phenyl acetic acid ($2\alpha < 0.01$) The median values are also clearly different (Table 1)

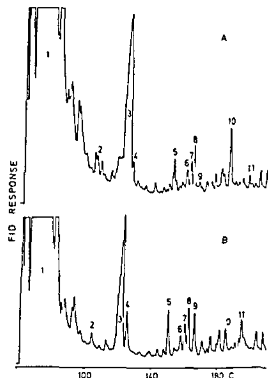

Fig 2 Typical GC profile from neonate boy A first day B third day 1 solvent front 2 3-OH butyric acid 3 urea 4 succinic acid 5 adipic acid 6 2-OH-glutaric acid 7 3 OH 3 Me glutaric acid 8 pimelic acid (int st) 9 4-OH phenylacetic acid 10 citric acid 11 hippuric acid

stadt Germany) Adipic acid pimelic acid 2-OH glutaric acid (Zn salt) were obtained from Koch Light Laboratories Ltd (Bucks England) 3 OH 3 Me glutaric acid was purchased from Sigma Chemical Company (St Louis Missouri U S) and citric acid from BDH Chemical Ltd (Poole England) Stationary phase for gas chromatography Dexsil 300 was obtained from Analabs Inc (North Haven Conn U S) and column support chromosorb W (HP) from Koch Light Laboratories Ltd BSTFA and Tri Sil were purchased from Pierce Chemical Co (Rockford Ill U S)

Analytical procedure

Urine samples containing 2 mg (17 5 µmol) creatinine were diluted with equal amounts of saturated NaCl solution and 200 µl of a 400 mg/l (2 5 mmol/l) pimelic acid solution The pH of the mixture was adjusted to 1 with 5 mol/l HCl prior to extraction Three consecutive extractions were made with both ethylether and ethylacetate The organic phases were dried (Na_2SO_4) and the solvent was evaporated in a stream of dry nitrogen The remanence was silylated to TMS-ethers/esters at room temperature with Tri Sil (200 µl) and BSTFA (200 µl) 2–8 hours after silylation 4 µl of the mixture was injected into a Hewlett Packard 5830 gas chromatograph The instrument was equipped with a flameionisation detector an integrator and a dedicated computer The column was a 1 8 m×3 mm (i d) glass coil packed with Dexsil 300 (3 %) on Chromosorb W (HP) The temperature of the column was programmed at 4 C/min from 60 C The helium carrier flow rate was 40 ml/min

An aqueous stock solution (50 ml) consisting of 3-OH butyric acid (Na salt 30 mg 265 µmol) succinic acid (25 mg 212 µmol) adipic acid (25 mg 171 µmol) 2-OH glutaric acid (Zn salt 45 mg 212 µmol) 3 OH 3 Me glutaric acid (50 mg 308 µmol) 4-OH phenylacetic acid (25 mg 164 µmol) and citric acid (125 mg 647 µmol) was used as standards in appropriate dilutions

The standards were analyzed according to the procedure described for urines Standard curves of the compounds were straight and through zero The variation coefficients calculated from double determinations on several concentration levels in the standards were 3-OH butyric acid 12 % succinic acid 15 % adipic acid 9 % 2 OH glutaric acid 7 % 3 OH 3 Me glutaric acid 7 % 4 OH phenylacetic acid 4 % and citric acid 8 % It was only possible in a few cases to make double determinations on the urine specimens from the children However these analyses indicated that the variation coefficients were in the same order of magnitude as in the standards from 10–15 %

The chemical structure as well as the gas chromatographic retention time of the internal standard pimelic acid are so similar to those of the compounds in question that the variation component due to variations in the extraction efficiency are minimal Recovery of the compounds was not quantitative but extraction efficiency was normalised with reference to pimelic acid

DISCUSSION

During the first hours of life glycogen stores are depleted (15) Thereafter, the primary source of calories is endogen fat This is reflected in the rapid rise in blood lipids (11) Protein catabolism contributes little to energy requirements (4) This particular metabolic situation seems to be reflected in the urinary excretion of non nitrogen organic acids as shown in Table 1 The excretion of the metabolites in the neonate is remarkably different *from the excretion in the adult* (2, 17) Comparing the results of Bjorkman et al (2) and the results obtained in the present study major disagreements are found as regards the excretion of succinic acid and citric acid (Table 1) In the work of Bjorkman et al succinic acid and fumaric acid did not separate in the gas chromatographic profile This fact might explain the difference in the concentrations of succinic acid No satisfactory explanation for the difference in citric acid excretion is available However, the nutritional condition of mother and child might have been different *Excretion of the organic acids in* vestigated in our study did not differ between the two days of collection with the exception of 4 OH phenylacetic acid the excretion of which increased *during the first four days* This most likely due to production by the establishing intestinal flora (6)

Taking into consideration the high blood concentration of fatty acids and ketone bodies in the newborn (11) the excretion of 3 OH *butyric acid in the first days of life* is remarkably low The reported levels of fatty acids and ketone bodies (11) are comparable to those in adult blood after one to two days of hunger, where substantial amounts of urinary 3 OH butyric acid are found (13 14) The impaired ability to develop ketonuria in the first period of life has been demonstrated by other investigators (7, 16) but the biological mechanism is still not understood

Succinic acid *is excreted in a variety of* ketotic conditions (12) and ketoacidosis in the neonate is accompanied by excretion of succinic acid (9)

The substantial amounts of adipic acid in the urines investigated most probably reflect the high lipolytic activity and increased catabolism *of fatty acids in the neonate* (11) This assumption is based on the observations of Pettersen et al (12) showing a positive correlation between the degree of ketosis and the excretion of adipic acid

In the neonate high plasma concentration (10) and urinary excretion (1, 2 3) of citric acid have been reported

The biological significance of the metabolic profiles reported awaits further investigations

TEMPORARY INTESTINAL LACTASE DEFICIENCY IN LIGHT TREATED JAUNDICED INFANTS

A F BAKKEN

From the Department of Paediatrics Rikshospitalet University of Oslo Oslo Norway

ABSTRACT Bakken A F (Department of Paediatrics Rikshospitalet University of Oslo Oslo Norway) Temporary intestinal lactase deficiency in light treated jaundiced infants Acta Paediatr Scand 66 91 1977.—The intestinal lactase activity in six newborn jaundiced light treated infants with diarrhea and in eight normal controls were compared by lactose tolerance test (LTT) The ability to hydrolyze lactose was minimal in the jaundiced infants during light treatment compared to the controls which could absorb lactose very well Peroral intestinal biopsies were taken from the newborn jaundiced infants during light treatment By histochemical technique no intestinal lactase activity was found in these intestines When the jaundiced infants with diarrhea were given lactose free diet the stools normalized The effect was reversed when breast milk was given while the baby was still jaundiced and light treated These findings indicate that the increased amounts of unconjugated bilirubin in the intestine of jaundiced infants during light treatment inhibit the intestinal brush border lactase When the icterus fades the lactase is again active The practical consequence is to give light treated infants lactose free diet if they get diarrhea and to reintroduce breast milk or other lactose containing diet when the baby is no longer icteric

KEY WORDS Light treatment intestinal lactase intestinal biopsy diarrhea in the newborn

Ever since Cremer et al (6) introduced light treatment of the newborn jaundiced infants loose greenish stools from some of these have been observed (18) The current explanation for these loose stools is vague they are said to be due to increased amounts of break down products from bile pigments excreted in the bile (18 19) However serious dehydration of these infants due to the diarrhea has not been reported and light treatment of jaundiced neonates is used throughout the world in spite of some of the disadvantages which have been described (20 24)

It has been found that the concentration of unconjugated bilirubin is increased in the bile and intestine during light treatment of jaundiced infants (4 19 21) Furthermore it has been shown that unconjugated bilirubin is able to uncouple oxidative phosphorylations and thereby decrease the energy formation intracellularly (5 29) An attractive hypothesis therefore is that the cause of the diarrhea in these infants might be a temporary inhibition of the intestinal brush border lactase by the increased amounts of unconjugated bilirubin in the intestine

The present study was performed to see if this theory could be substantiated different groups of neonates had their ability to hydrolyze and absorb lactose investigated Diets both containing lactose and lactose free were given to see the effect upon the stools of the newborn babies

ABSTRACT Bakken A F (Department of Paediatrics Rikshospitalet University of Oslo Oslo Norway) Temporary intestinal lactase deficiency in light treated jaundiced infants Acta Paediatr Scand 66 91 1977.—The intestinal lactase activity in six newborn jaundiced light treated infants with diarrhea and in eight normal controls were compared by lactose tolerance test (LTT) The ability to hydrolyze lactose was minimal in the jaundiced infants during light treatment compared to the controls which could absorb lactose very well Peroral intestinal biopsies were taken from the newborn jaundiced infants during light treatment By histochemical technique no intestinal lactase activity was found in these intestines When the jaundiced infants with diarrhea were given lactose free diet the stools normalized The effect was reversed when breast milk was given while the baby was still jaundiced and light treated These findings indicate that the increased amounts of unconjugated bilirubin in the intestine of jaundiced infants during light treatment inhibit the intestinal brush border lactase When the icterus fades the lactase is again active The practical consequence is to give light treated infants lactose free diet if they get diarrhea and to reintroduce breast milk or other lactose containing diet when the baby is no longer icteric

KEY WORDS Light treatment intestinal lactase intestinal biopsy diarrhea in the newborn

Ever since Cremer et al (6) introduced light treatment of the newborn jaundiced infants loose greenish stools from some of these have been observed (18) The current explanation for these loose stools is vague they are said to be due to increased amounts of break down products from bile pigments excreted in the bile (18 19) However serious dehydration of these infants due to the diarrhea has not been reported and light treatment of jaundiced neonates is used throughout the world in spite of some of the disadvantages which have been described (20 24)

It has been found that the concentration of unconjugated bilirubin is increased in the bile and intestine during light treatment of jaundiced infants (4 19 21) Furthermore it has been shown that unconjugated bilirubin is able to uncouple oxidative phosphorylations and thereby decrease the energy formation intracellularly (5 29) An attractive hypothesis therefore is that the cause of the diarrhea in these infants might be a temporary inhibition of the intestinal brush border lactase by the increased amounts of unconjugated bilirubin in the intestine

The present study was performed to see if this theory could be substantiated different groups of neonates had their ability to hydrolyze and absorb lactose investigated Diets both containing lactose and lactose free were given to see the effect upon the stools of the newborn babies

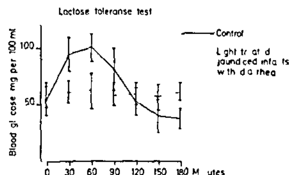

Fig 1 Lactose tolerance test (LTT) performed on 6 new born jaundiced infants with diarrhea during light treatment LTT from 8 normal controls are shown for comparison ±one standard deviation is shown for each value

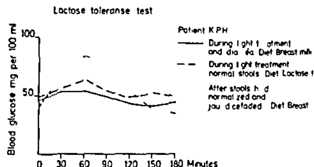

Fig 2 Lactose tolerance test performed on one newborn jaundiced infant at three different occasions during light treatment while the patient had diarrhea and was given breast milk during light treatment while the stools were normalized because of a lactose free diet and after the jaundice had faded the stools were normalized and breast milk was reintroduced

MATERIALS AND METHODS

Six newborn caucasian infants with physiological jaundice (no Rhesus or ABO incompatibility) were studied They all had serum bilirubin above 10 mg/100 ml (measured by Jendrassik & Gróf's method (13) on the second day of life and they were put under light (130 footcandles light unit equipped with 10 white 20 Watt fluorescent bulbs) During the light treatment these six infants developed diarrhea (more than six loose stools per 24 hours) Peroral intestinal biopsy was performed on these infants during the second or third day of life A double loop hydraulic capsule was used (2) and the biopsies were taken close to the ligament of Treitz The biopsies were investigated with hematoxiline/eosine staining and histochemically for brush border lactase using the method described by Lojda et al (17) Lactose tolerance tests (LTT) were performed on these six infants during the second or third day of life Because of the possible false results obtained by oral administration of lactose (16) lactose in a concentration of 2 g/kg body wieght of the infants was installed directly into the stomach Blood glucose was measured by Hultman s method (12) at times zero 30 60 90 120 150 and 180 minutes after the lactose had been given

After two days in the light while the diarrhea still persisted these six infants were given lactose free diets (AL 110® Nestlé) for three days After this period breast milk was reintroduced Their numbers of stools were observed over this period

A LTT was also performed in three of these infants during the period of lactose free diet and another after the jaundice had faded and the stools had normalized on breast milk

Eight normal newborn babies were used as controls These infants were all of the same race and in the same weightrange as the jaundiced infants (3–4 kg) however none of them had serum bilirubin above 10 mg/100 ml at any time and none had diarrhea during the first week of life They were all fed exclusively on breast milk A LTT was performed on these infants during the second or third day of life Peroral intestinal biopsies were not performed

Normal intestinal brush border lactase was looked for by the same histochemical technique of Lojda et al (17) in a two-year-old girl whose coeliac disease was now controlled after a period of gluten free diet

To test the effect of bilirubin on the intestinal lactase in vitro slices from the biopsy specimen of the normal intestine were incubated in a solution of bilirubin (15 mg/100 bilirubin Hoffman La Roche B 509289 in isotonic sodiumbicarbonate pH (8 3)) for 30 minutes prior to the application of the histochemical technique

RESULTS

Lactose tolerance test

Fig 1 shows the results of the LTT performed in the light treated jaundiced infants during their period of diarrhea on the second or third day of life The LTT from the control infants are shown for comparison

Fig 2 gives the results from the LTT performed on one of the six jaundiced light

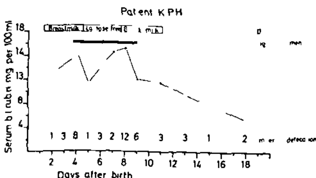

Fig 3 The numbers of defecations and the serum bilirubin level are shown in a patient with physiological jaundice The duration of light treatment and the different diets in this period are indicated

Fig 4 Duodenal mucosa from a two day old jaundiced light treated infant with diarrhea (Hem eos x 50)

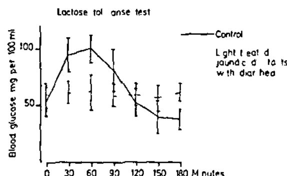

Fig 1 Lactose tolerance test (LTT) performed on 6 new born jaundiced infants with diarrhea during light treat ment LTT from 8 normal controls are shown for com parison ±one standard deviation is shown for each value

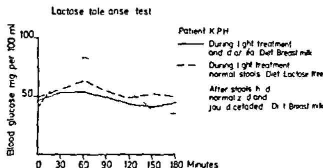

Fig 2 Lactose tolerance test performed on one newborn jaundiced infant at three different occasions during light treatment while the patient had diarrhea and was given breast milk during light treatment while the stools were normalized because of a lactose free diet and after the jaundice had faded the stools were normalized and breast milk was reintroduced

MATERIALS AND METHODS

Six newborn caucasian infants with physiological jaun dice (no Rhesus or ABO incompatibility) were studied They all had serum bilirubin above 10 mg/100 ml (meas ured by Jendrassik & Gróf's method (13) on the second day of life and they were put under light (130 footcandles light unit equipped with 10 white 20 Watt fluorescent bulbs) During the light treatment these six infants de veloped diarrhea (more than six loose stools per 24 hours) Peroral intestinal biopsy was performed on these infants during the second or third day of life A double loop hy draulic capsule was used (2) and the biopsies were taken close to the ligament of Treitz The biopsies were in vestigated with hematoxiline/eosine staining and histo-chemically for brush border lactase using the method described by Lojda et al (17) Lactose tolerance tests (LTT) were performed on these six infants during the second or third day of life Because of the possible false results obtained by oral administration of lactose (16) lactose in a concentration of 2 g/kg body wieght of the infants was installed directly into the stomach Blood glucose was measured by Hultman s method (12) at times zero 30 60 90 120 150 and 180 minutes after the lac tose had been given

After two days in the light while the diarrhea still per sisted these six infants were given lactose free diets (AL 110® Nestlé) for three days After this period breast milk was reintroduced Their numbers of stools were ob-served over this period

A LTT was also performed in three of these infants during the period of lactose free diet and another after the jaundice had faded and the stools had normalized on breast milk

Eight normal newborn babies were used as controls These infants were all of the same race and in the same weightrange as the jaundiced infants (3–4 kg) however none of them had serum bilirubin above 10 mg/100 ml at any time and none had diarrhea during the first week of life They were all fed exclusively on breast milk A LTT was performed on these infants during the second or third day of life Peroral intestinal biopsies were not performed

Normal intestinal brush border lactase was looked for by the same histochemical technique of Lojda et al (17) in a two-year old girl whose coeliac disease was now con trolled after a period of gluten free diet

To test the effect of bilirubin on the intestinal lactase in vitro slices from the biopsy specimen of the normal intestine were incubated in a solution of bilirubin (15 mg/100 bilirubin Hoffman La Roche B 509289 in isotonic sodiumbicarbonate pH (8 3)) for 30 minutes prior to the application of the histochemical technique

RESULTS

Lactose tolerance test

Fig 1 shows the results of the LTT performed in the light treated jaundiced infants during their period of diarrhea on the second or third day of life The LTT from the control infants are shown for comparison

Fig 2 gives the results from the LTT per formed on one of the six jaundiced light

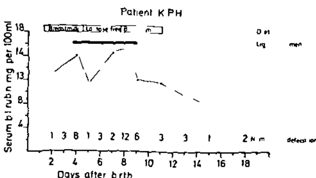

Fig 3 The numbers of defecations and the serum bili rubin level are shown in a patient with physiological jaundice The duration of light treatment and the different diets in this period are indicated

Fig 5 Duodenal mucosa from a two year old infant The mucosa is investigated histochemically for brush border lactase The enzyme activity is shown as black colour at the intestinal villi (×36)

treated infants at three different occasions During light treatment while the diet was breast milk and the stools were loose during light treatment after the stools had normalized and the infant was on lactose free diet and after the jaundice had faded and the infant was back on breast milk The details of the observations from the same baby are shown in Fig 3 The serum bilirubin levels are indicated from day 2 to day 18 after birth the number of defaecations each day recorded and the diet on the different days and the period of light treatment are shown The drastic reduction in the number of defaecations and at the same time a normalizing of the stools when lactose free diet was given instead of breast milk was typical for all the six infants in this group The reappearance of loose stools when breast milk was reintroduced with the infant still on light treatment was also a common finding

Intestinal biopsies

A typical picture of the mucosa from the duodeno-jejunal region of a two-day old jaundiced infant is shown in colour in Fig 4 The mucosa is icteric and the villi are very different from what we are used to see in normal though older infants (see Fig 5 for comparison) The villi are almost absent or at least rudimentary The surface epithelium is cuboidal containing mucous as are the glands inside the mucosa There is no cellular infiltration This picture of a yellow mucosa and almost no normal villi was a constant finding in the jaundiced light treated infants during their diarrheal periods The application of the histochemical method for lactase is shown in Figs 5 and 6 Fig 5 shows the activity of lactase as black colour on the surface of the villi in the duodenal mucosa of a two-year old girl whose mucosa was normalized after 9 months on gluten free diet Fig 6 reveals no lactase activity in the mucosa of one of the newborn jaundiced infants with diarrhea While Fig 5 shows long normal villi in the two year old girl Fig 6 shows as in Fig 4 an almost total lack of normal villi in the jaundiced infant with icteric mucosa

When the biopsy specimen of the normal two year old girl was pretreated with bilirubin in vitro for 30 minutes no lactase activity was found afterwords while the structure of the mucosa remained intact

DISCUSSION

The difference between the absorption of lactose in jaundiced infants during diarrheal periods when on light treatment and normal infants (Fig 1) is significant It has been found

Fig 5 Duodenal mucosa from a two year old infant The mucosa is investigated histochemically for brush border lactase The enzyme activity is shown as black colour at the intestinal villi (×36)

treated infants at three different occasions During light treatment while the diet was breast milk and the stools were loose during light treatment after the stools had normalized and the infant was on lactose free diet and after the jaundice had faded and the infant was back on breast milk The details of the observations from the same baby are shown in Fig 3 The serum bilirubin levels are indicated from day 2 to day 18 after birth the number of defaecations each day recorded and the diet on the different days and the period of light treatment are shown The drastic reduction in the number of defaecations and at the same time a normalizing of the stools when lactose free diet was given instead of breast milk was typical for all the six infants in this group The reappearance of loose stools when breast milk was reintroduced with the infant still on light treatment was also a common finding

Intestinal biopsies

A typical picture of the mucosa from the duodeno-jejunal region of a two-day old jaundiced infant is shown in colour in Fig 4 The mucosa is icteric and the villi are very different from what we are used to see in normal though older infants (see Fig 5 for comparison) The villi are almost absent or at least rudimentary The surface epithelium is cuboidal containing mucous as are the glands inside the mucosa There is no cellular infiltration This picture of a yellow mucosa and almost no normal villi was a constant finding in the jaundiced light treated infants during their diarrheal periods The application of the histochemical method for lactase is shown in Figs 5 and 6 Fig 5 shows the activity of lactase as black colour on the surface of the villi in the duodenal mucosa of a two-year old girl whose mucosa was normalized after 9 months on gluten free diet Fig 6 reveals no lactase activity in the mucosa of one of the newborn jaundiced infants with diarrhea While Fig 5 shows long normal villi in the two year old girl Fig 6 shows as in Fig 4 an almost total lack of normal villi in the jaundiced infant with icteric mucosa

When the biopsy specimen of the normal two-year old girl was pretreated with bilirubin in vitro for 30 minutes no lactase activity was found afterwords while the structure of the mucosa remained intact

DISCUSSION

The difference between the absorption of lactose in jaundiced infants during diarrheal periods when on light treatment and normal infants (Fig 1) is significant It has been found

Fig 5 Duodenal mucosa from a two year old infant The mucosa is investigated histochemically for brush border lactase The enzyme activity is shown as black colour at the intestinal villi (×36)

DISCUSSION

The difference between the absorption of lac tose in jaundiced infants during diarrheal periods when on light treatment and normal infants (Fig 1) is significant It has been found

give energy to hydrolyzing reactions deteriorates Another way of inhibition of the lactase by the unconjugated bilirubin may be through reduction of ATP ase activity (19) or an effect more basically on the nucleic acids (24)

Supporting the results presented in this paper are the findings of Yeung (28) He describes a significant inverse correlation between the serum bilirubin level and the blood sugar in the first four days of life This might be an indirect clue to the inhibition of the intestinal lactase by unconjugated bilirubin

Regardless the mechanism of lactase dysfunction during light treatment of the newborn baby the increased amount of unconjugated bilirubin in the intestine during light treatment makes lactose-containing diet unsuitable for these babies and such food ought to be replaced by lactose free diet to avoid possible complications from the loose stools The mothers should be encouraged to pump out their milk during this period and be told that the breast feeding can be started again as soon as the baby is out of the light box

Fig 6 Duodenal mucosa investigated histochemically for brush border lactase in a two day old jaundiced light treated infant with diarrhea No activity is seen (for normal activity see Fig 5) (×36)

by other investigators (15 21) that there is a fairly good correlation between LTT and the lactase activity in the intestine measured by non histochemical means It is therefore obvious that there is an impaired ability in the jaundiced light treated infants to absorb lactose This disability is not exclusively due to increased rate of transport of the intestinal content, as Fig 2 shows the LTT is lower even if the stools are normal on lactose free diet as long as the infant is jaundiced

Furthermore the flat LTT of the jaundiced newborn is obviously abnormal when compared to normal newborn infants and even premature babies (Fig 1 (3 15)) Boellner et al (3) showed that the LTT might be influenced by the amount of lactose given in the period before the LTT is performed This cannot play an important part in a two day old infant However, the inductibility of intestinal brush border lactase is still an object of discussion (10, 16)

The great variation in the number of stools with the different types of diet is shown in Fig 3 The number of stools normalized when lactose was excluded from the diet This is an indirect clue for what is shown by the LTT In these jaundiced light treated newborn infants the ability to hydrolyze lactose is minimal

The complete lack of intestinal lactase activity shown in Fig 6 is in contrast to what has been found in spontaneous abortions and in stillborn babies (1 8) This was anticipated from studies of the structure of the intestine as it has been found that the lactase activity is localized strictly to the brush border epithelium (7) and that the lactase activity is especially vulnerable when structural changes occur in the intestinal epithelium (11) To verify this intestinal biopsies from normal newborn infants ought to have been studied However I did not feel I had the ethical right to perform such investigations on normal babies even if the complications from intestinal biopsies generally are very rare (27)

The mechanism of decreased activity of intestinal lactase during light treatment of jaundiced babies might be inhibition by the bilirubin in the intestinal mucosa The cause of the diarrhea in these infants has been said to be toxic breakdown products (18) without any further explanation It has been shown that the amount of unconjugated bilirubin in the bile and thus in the intestine increases during light treatment (4 19 21) An extra amount of bilirubin might concentrate in the mucosa because it binds to ligandin (14) The mechanism of inhibiting the hydrolyzing enzyme lactase is not clear Bilirubin might effect the oxidative phosphorylating reactions (9 26) By a slower rate of the oxidative phosphorylation the production of energy intramitochondrially decreases and the ability to

give energy to hydrolyzing reactions deteriorates Another way of inhibition of the lactase by the unconjugated bilirubin may be through reduction of ATP ase activity (19) or an effect more basically on the nucleic acids (24)

Supporting the results presented in this paper are the findings of Yeung (28) He describes a significant inverse correlation between the serum bilirubin level and the blood sugar in the first four days of life This might be an indirect clue to the inhibition of the intestinal lactase by unconjugated bilirubin

Regardless the mechanism of lactase dysfunction during light treatment of the newborn baby the increased amount of unconjugated bilirubin in the intestine during light treatment makes lactose containing diet unsuitable for these babies and such food ought to be replaced by lactose free diet to avoid possible complications from the loose stools The mothers should be encouraged to pump out their milk during this period and be told that the breast feeding can be started again as soon as the baby is out of the light box

Fig 6 Duodenal mucosa investigated histochemically for brush border lactase in a two day old jaundiced light treated infant with diarrhea No activity is seen (for normal activity see Fig 5) (×36)

by other investigators (15 21) that there is a fairly good correlation between LTT and the lactase activity in the intestine measured by non histochemical means It is therefore obvious that there is an impaired ability in the jaundiced light treated infants to absorb lactose This disability is not exclusively due to increased rate of transport of the intestinal content as Fig 2 shows the LTT is lower even if the stools are normal on lactose free diet as long as the infant is jaundiced

Furthermore the flat LTT of the jaundiced newborn is obviously abnormal when compared to normal newborn infants and even premature babies (Fig 1 (3 15)) Boellner et al (3) showed that the LTT might be influenced by the amount of lactose given in the period before the LTT is performed This cannot play an important part in a two day old infant However the inductibility of intestinal brush border lactase is still an object of discussion (10 16)

The great variation in the number of stools with the different types of diet is shown in Fig 3 The number of stools normalized when lactose was excluded from the diet This is an indirect clue for what is shown by the LTT In these jaundiced light treated newborn infants the ability to hydrolyze lactose is minimal

The complete lack of intestinal lactase activity shown in Fig 6 is in contrast to what has been found in spontaneous abortions and in stillborn babies (1 8) This was anticipated from studies of the structure of the intestine as it has been found that the lactase activity is localized strictly to the brush border epithelium (7) and that the lactase activity is especially vulnerable when structural changes occur in the intestinal epithelium (11) To verify this intestinal biopsies from normal newborn infants ought to have been studied However I did not feel I had the ethical right to perform such investigations on normal babies even if the complications from intestinal biopsies generally are very rare (27)

The mechanism of decreased activity of intestinal lactase during light treatment of jaundiced babies might be inhibition by the bilirubin in the intestinal mucosa The cause of the diarrhea in these infants has been said to be toxic breakdown products (18) without any further explanation It has been shown that the amount of unconjugated bilirubin in the bile and thus in the intestine increases during light treatment (4 19 21) An extra amount of bilirubin might concentrate in the mucosa because it binds to ligandin (14) The mechanism of inhibiting the hydrolyzing enzyme lactase is not clear Bilirubin might effect the oxidative phosphorylating reactions (9 26) By a slower rate of the oxidative phosphorylation the production of energy intramitochondrially decreases and the ability to

give energy to hydrolyzing reactions deteriorates Another way of inhibition of the lactase by the unconjugated bilirubin may be through reduction of ATP ase activity (19) or an effect more basically on the nucleic acids (24)

Supporting the results presented in this paper are the findings of Yeung (28) He describes a significant inverse correlation between the serum bilirubin level and the blood sugar in the first four days of life This might be an indirect clue to the inhibition of the intestinal lactase by unconjugated bilirubin

Regardless the mechanism of lactase dysfunction during light treatment of the newborn baby the increased amount of unconjugated bilirubin in the intestine during light treatment makes lactose containing diet unsuitable for these babies and such food ought to be replaced by lactose free diet to avoid possible complications from the loose stools The mothers should be encouraged to pump out their milk during this period and be told that the breast feeding can be started again as soon as the baby is out of the light box

CONCENTRATION OF THYROGLOBULIN IODINE CONTENTS OF THYROGLOBULIN AND OF IODOAMINOACIDS IN HUMAN NEONATES THYROID GLANDS

NICOLE ETLING

From the Unite 30 INSERM Hopital des Enfants Malades Paris France

ABSTRACT Etling N (Unite 30 INSERM Hopital des Enfants Malades Paris France) Concentration of thyroglobulin iodine contents of thyroglobulin and iodoamino acids in human neonates thyroid glands Acta Paediatr Scand 66 97 1977.—The iodine and protein concentrations the iodoamino acids content of thyroglobulin (TG) were determined in 17 thyroid tissues from human neonates who died from 3 hours to 47 days after birth Total iodine concentration of neonate tissues increased with life duration TG concentration was related to the survival duration of the neonates Increase of the iodine content was associated to the increase of the TG content mean value was 0 16 μg ^{127}I/100 μg TG in neonates who died within the first 20 hours after birth 0 25 μg in neonates who survived 26 to 72 hours and 0 43 μg in neonates living more than 10 days Expressed as iodine content to total iodine ratio iodoamino acid percentages were not related to the iodine concentration of the tissue When the iodoamino acids were expressed in residues per molecule of TG iodotyrosines thyroxine and triiodothyronine increased with duration of survival These variations in iodine content and concentration of thyroglobulin could be related to acute hormonal changes in serum observed in early neonatal period

KEY WORDS Newborn thyroid tissue iodoamino acids thyroglobulin

In the human newborn the immediate and early post natal period is associated with a variety of acute changes in several aspects of thyroid hormone economy Within the first few minutes of extra uterine life serum thyrotrophin (TSH) concentration increases markedly (10 4) several hours later the serum 3 5 3 triiodothyronine (T_3) rises sharply (1) followed by an increase in serum thyroxine (T_4) (5) Knowledge of these alterations is derived entirely from the numerous measurements that have been made in the blood Little is known in contrast about the changes which may be occuring within the thyroid gland during the same general period In 1938 Palmer (17) using a microchemical technique measured the total iodine and T_4 content of the thyroid in a series of 7 month fetuses to 12 days old infants The ratio of T_4 iodine to total iodine was found to be essentially the same as in normal adults Recently Fisher and co-workers (11) using radioimmunoassay studied the ratio of T_4 to T_3 in the thyroid gland of abortuses the oldest of which were at 26 and 31 weeks of gestation In all the ratios were similar to those reported in euthyroid adults

We have recently shown (8) that in neonatal thyroid tissue both the colloid content and the iodine content of extracted proteins displays transient variations during the neonatal period These variations appear to be more closely related to survival time following birth than to gestational age at birth In the present report we examine the concentration of thyro

Table 2 *Means and standard deviations of iodine and iodoamino acid content of thyroglobulin (TG) in thyroid tissue from human neonates*

Group	TG iodine (μg ^{127}I/ 100 μg TG)	Iodoamino acid content (residues/mole TG)			
		MIT	DIT	T	T_3
I	0 16±0 11	2 35±1 41	1 71±1 27	0 61±0 44	0 03±0 03
II	0 25±0 11	3 51±1 36	2 38±1 01	1 16±0 49	0 06±0 08
III	0 43±0 05	5 85±0 59	4 18±0 59	1 84±0 38	0 30±0 03

analysis because of the far lesser sensitivity of the latter

The second gel of the pair was stained with 0 5% amidoblack in 2% acetic acid and destained with 7% acetic acid until complete decoloration of the background was obtained The stained proteins were scanned in a Gilford spectrophotometer at 610 nm using a recorder fitted with a linear transport attachment The percentage of thyroglobulin was calculated either from the weight of several protein peaks found on the scan itself or by planimetry and good proportionality between the height of a peak and content of protein was obtained with quantities of protein between 5 and 40 μg

For the measurement of the absolute concentration of the several iodoamino acids the small amount of thyroid tissue available and its low iodine content precluded the use of classical techniques and an alternate method of greater sensitivity was employed Hydrolysis of the NaCl soluble extracts was performed either with Pronase (13) or with Pronase Leucylamino-peptidase (18) there was no difference between the results of the two digestion techniques probably because of the low iodine content of the extracts An aliquot of the hydrolysate containing around 100 ng iodine was applied to Whatman 1 paper together with μl bromophenol blue (1 mg/ml) to serve as a marker Chromatograms were developed in *n* butanol acetic acid water (78 5 17) and *n* butanol saturated with ? N ammonium hydroxide After chromatography each strip was cut into 1×3 cm segments and these were ashed in separate tubes using the sulfonitroperchloric mixture Iodine contents were then measured as described earlier The ng iodine values were calculated from the spectrophotometric peaks and the percentages evaluated Recovery of the known amounts of the iodine applied to each chromatographic strip was nearly complete

The percentage of iodide in the soluble extracts was also evaluated by paper electrophoresis (1 hour at 300 v in 0 M ammonium carbonate pH 8 4) ^{127}I determinations were done as previously described and good concordance with the results of chromatography was observed

All chromatographic electrophorectic and iodine analyses were performed at least twice for each specimen

RESULTS

Iodine and thyroglobulin concentrations

The total iodine concentration in the thyroids of neonates was far lower than in thyroid tissue of adults (Table 1) Mean values were lowest in Group I (6 25±4 96 μg/100 mg mean ±S D) increased slightly in Group II (9 28±4 65) and demonstrated a pronounced increase in Group III (26 30±4 50) which had the longest post natal survival time For the group of neonates as a whole there was a significant correlation between thyroid iodine concentration and survival time ($r=0\ 61$ $p<0\ 01$)

These changes in total iodine concentration were the resultant of two factors The first was an increase in the thyroglobulin concentration with time values changing from 1 43 mg/100 mg±0 88 in Group I to 1 92±0 77 in Group II and significantly to 3 20±0 20 in Group III ($r=0\ 49$ $p<0\ 05$) However even in Group III thyroids the concentration of thyroglobulin was well below that found in adult glands (9 53±2 83) (unpublished data)

The second factor associated with the increase in thyroid iodine concentration was an

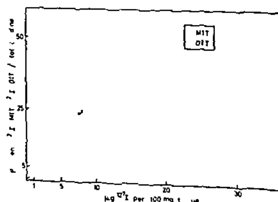

Fig 1 Relationship between thyroid tissues iodine content and monoiodotyrosine and diiodotyrosine percentage in human neonates

globulin as well as its iodine and individual iodoamino acid contents in the thyroids of the same neonates

MATERIAL

Thyroid glands from 17 neonates ranging from 26 to 37 weeks in gestational age were obtained at autopsies performed between 2 and 16½ hours following death (mean 10 hours) during which time the specimens were kept at 4 In Table 1 the various thyroid samples are arranged according to the survival time (3 hours 10 minutes to 49 days) Group I includes the thyroid glands of neonates who survived less than 20 hours Group II comprises those with a survival time between 26 and 72 hours and Group III includes the thyroids of neonates who lived for more than 10 days All biochemical analyses were performed in one lobe the other being used for histological examination Lobe weights varied from 210 to 610 mg except in specimen no 1 which weighed 2 g

METHODS

As soon as the thyroid was removed the tissue was frozen at – 20° until used Soluble proteins were obtained by extracting thyroid slices with 0 14 M NaCl (200 mg wet tissue per ml) and centrifuging the extract at 8 000 x g for 20 min in a refrigerated MSE centrifuge The tissue pellet was solubilized with N NaOH and diluted The volumes of both the soluble supernatants and the accompanying pellets were determined [127]I content was measured using a semi automatic micromethod Each sample was digested at 245 for 30 min with a mixture of concentrated sulfonitroperchloric acids After dilution stable iodine was determined using the ceric arsenious reaction in a Technicon Autoanalyser (14) The method is applicable in the range of 1 to 10 ng iodine per sample with a precision of 5%

The protein content of the soluble extract was evaluated by measuring the absorption at 260 and 280 nm (20) and by the method of Folin (16) Values obtained with the two methods aggreed closely

The separation of thyroglobulin from the other soluble proteins was performed by electrophoresis in a 5% polyacrylamide gel using a Pleuger apparatus according to the method of Barka (2) The buffer employed was Tris glycine 0 02 M pH 8 3 An aliquot of the soluble extract containing about 50–100 μg protein and 300 ng iodine was overlaid in 50 μl of 10% sucrose on the top of the gel great care was exercised in applying the sample as stacking gel was not used Electrophoresis was carried out for about 1 hour at a current of 3 mA per tube

Duplicate gels of about 7 cm length were prepared The first gel was cut in a slicer into 1 3 mm pieces Each slice was placed into a calibrated glass tube and dissolved in 0 15 ml 30% H_2O_2 at 48 during 20 hours The dissolved gels were adjusted to a volume of 0 5 ml and the iodine concentration measured in aliquots Blank measurements in solubilized gel alone were nil This technique was employed instead of sucrose density gradient

RESULTS

Iodine and thyroglobulin concentrations

The total iodine concentration in the thyroids of neonates was far lower than in thyroid tissue of adults (Table 1) Mean values were lowest in Group I (6 25±4 96 μg/100 mg mean ±S D) increased slightly in Group II (9 28± 4 65) and demonstrated a pronounced increase in Group III (26 30±4 50) which had the longest post natal survival time For the group of neonates as a whole there was a significant correlation between thyroid iodine concentration and survival time ($r=0\ 61$ $p<0\ 01$)

These changes in total iodine concentration were the resultant of two factors The first was an increase in the thyroglobulin concentration with time values changing from 1 43 mg/ 100 mg±0 88 in Group I to 1 92±0 77 in Group II and significantly to 3 20±0 20 in Group III ($r=0\ 49$ $p<0\ 05$) However even in Group III thyroids the concentration of thyroglobulin was well below that found in adult glands (9 53±2 83) (unpublished data)

The second factor associated with the increase in thyroid iodine concentration was an

globulin as well as its iodine and individual iodoamino acid contents in the thyroids of the same neonates

MATERIAL

Thyroid glands from 17 neonates ranging from 26 to 37 weeks in gestational age were obtained at autopsies performed between 2 and 16½ hours following death (mean 10 hours) during which time the specimens were kept at 4 In Table 1 the various thyroid samples are arranged according to the survival time (3 hours 10 minutes to 49 days) Group I includes the thyroid glands of neonates who survived less than 20 hours Group II comprises those with a survival time between 26 and 72 hours and Group III includes the thyroids of neonates who lived for more than 10 days All biochemical analyses were performed in one lobe the other being used for histological examination Lobe weights varied from 210 to 610 mg except in specimen no 1 which weighed 2 g

METHODS

As soon as the thyroid was removed the tissue was frozen at −20 until used Soluble proteins were obtained by extracting thyroid slices with 0 14 M NaCl (200 mg wet tissue per ml) and centrifuging the extract at 8 000 x g for 20 min in a refrigerated MSE centrifuge The tissue pellet was solubilized with N NaOH and diluted The volumes of both the soluble supernatants and the accompanying pellets were determined ^{127}I content was measured using a semi automatic micromethod Each sample was digested at 245 for 30 min with a mixture of concentrated sulfonitroperchloric acids After dilution stable iodine was determined using the ceric arsenious reaction in a Technicon Autoanalyser (14) The method is applicable in the range of 1 to 10 ng iodine per sample with a precision of 5%

The protein content of the soluble extract was evaluated by measuring the absorption at 260 and 280 nm (20) and by the method of Folin (16) Values obtained with the two methods agreed closely

The separation of thyroglobulin from the other soluble proteins was performed by electrophoresis in a 5% polyacrylamide gel using a Pleuger apparatus according to the method of Barka (2) The buffer employed was Tris glycine 0 02 M pH 8 3 An aliquot of the soluble extract containing about 50–100 μg protein and 300 ng iodine was overlaid in 50 μl of 10% sucrose on the top of the gel great care was exercised in applying the sample as stacking gel was not used Electrophoresis was carried out for about 1 hour at a current of 3 mA per tube

Duplicate gels of about 7 cm length were prepared The first gel was cut in a slicer into 1 3 mm pieces Each slice was placed into a calibrated glass tube and dissolved in 0 15 ml 30% H_2O_2 at 48 during 20 hours The dissolved gels were adjusted to a volume of 0 5 ml and the iodine concentration measured in aliquots Blank measurements in solubilized gel alone were nil This technique was employed instead of sucrose density gradient

Table 2 *Means and standard deviations of iodine and iodoamino acid content of thyroglobulin (TG) in thyroid tissue from human neonates*

Group	TG iodine (μg ^{127}I/ 100 μg TG)	Iodoamino acid content (residues/mole TG) MIT	DIT	T	T_3
I	0 16±0 11	2 35±1 41	1 71±1 27	0 61±0 44	0 03±0 03
II	0 25±0 11	3 51±1 36	2 38±1 01	1 16±0 49	0 06±0 08
III	0 43±0 05	5 85±0 59	4 18±0 59	1 84±0 38	0 30±0 03

analysis because of the far lesser sensitivity of the latter

The second gel of the pair was stained with 0 5% amidoblack in ?% acetic acid and destained with 7% acetic acid until complete decoloration of the background was obtained The stained proteins were scanned in a Gilford spectrophotometer at 610 nm using a recorder fitted with a linear transport attachment The percentage of thyroglobulin was calculated either from the weight of several protein peaks found on the scan itself or by planimetry and good proportionality between the height of a peak and content of protein was obtained with quantities of protein between 5 and 40 μg

For the measurement of the absolute concentration of the several iodoamino acids the small amount of thyroid tissue available and its low iodine content precluded the use of classical techniques and an alternate method of greater sensitivity was employed Hydrolysis of the NaCl soluble extracts was performed either with Pronase (13) or with Pronase Leucylamino-peptidase (18) there was no difference between the results of the two digestion techniques probably because of the low iodine content of the extracts An aliquot of the hydrolysate containing around 100 ng iodine was applied to Whatman 1 paper together with ? μl bromophenol blue (1 mg/ml) to serve as a marker Chromatograms were developed in n butanol acetic acid water (78 5 17) and n butanol saturated with ? N ammonium hydroxide After chromatography each strip was cut into 1×3 cm segments and these were ashed in separate tubes using the sulfonitroperchloric mixture Iodine contents were then measured as described earlier The ng iodine values were calculated from the spectrophotometric peaks and the percentages evaluated Recovery of the known amounts of the iodine applied to each chromatographic strip was nearly complete

The percentage of iodide in the soluble extracts was also evaluated by paper electrophoresis (1 hour at 300 v in 0 ? M ammonium carbonate pH 8 4) ^{1} I determinations were done as previously described and good concordance with the results of chromatography was observed

All chromatographic electrophorectic and iodine analyses were performed at least twice for each specimen

RESULTS

Iodine and thyroglobulin concentrations

The total iodine concentration in the thyroids of neonates was far lower than in thyroid tissue of adults (Table 1) Mean values were lowest in Group I (6 25±4 96 μg/100 mg mean ±S D) increased slightly in Group II (9 28±4 65) and demonstrated a pronounced increase in Group III (26 30±4 50) which had the longest post natal survival time For the group of neonates as a whole there was a significant correlation between thyroid iodine concentration and survival time (r=0 61 p<0 01)

These changes in total iodine concentration were the resultant of two factors The first was an increase in the thyroglobulin concentration with time values changing from 1 43 mg/100 mg±0 88 in Group I to 1 92±0 77 in Group II and significantly to 3 20±0 20 in Group III (r=0 49 p<0 05) However even in Group III thyroids the concentration of thyroglobulin was well below that found in adult glands (9 53±2 83) (unpublished data)

The second factor associated with the increase in thyroid iodine concentration was an

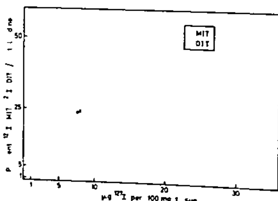

Fig 1 Relationship between thyroid tissues iodine content and monoiodotyrosine and diiodotyrosine percentage in human neonates

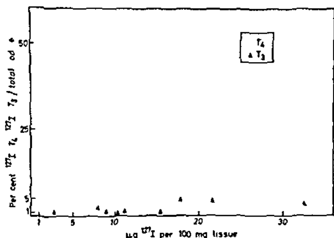

Fig 2 Relationship between thyroid tissues iodine content and hormones percentage in human neonates

increase in the iodine content of thyroglobulin (TG) itself (Table 2) Mean values were 0 16± 0 11 μg ^{127}I/100 μg TG in Group I 0 25±0 11 in Group II and 0 43±0 05 in Group III Owing to the large increase in values found in Group III for the three groups as a whole there was a positive correlation of iodine content in thyroglobulin with neonatal survival time that was of borderline statistical significance ($r=0\ 49$ $p=0\ 05$)

Content of iodoamino acids

When calculated on the basis of their iodine content relative to total iodine the proportions of mono and diiodotyrosine (MIT and DIT) did not vary among the three groups of neonates In the case of MIT percentages ranged between 17 and 30 with a mean of 23±5 In the case of DIT percentages varied between 15 and 41, with a mean of 30±6 The disperson of percentages was slightly larger for DIT than for MIT, the percentages of MIT and that of DIT were not correlated with the iodine concentration of the tissue (Fig 1)

Similarly no marked systematic variation with survival time and hence with thyroid iodine concentration was seen in the fraction of total thyroid iodine contributed by T_4 (Fig 2) values ranging between 18 and 34% of total iodine, with a mean of 27±5

As would be expected from the foregoing relationships, calculated values for the number of residues of each of these three iodinated amino acids increased progressively with increasing duration of survival (Table 2) As judged from analysis of variance, these changes with time were statistically significant (for MIT $p<0\ 01$, for DIT $0\ 01<p<0\ 05$ and for T_4 $p=0\ 01$)

Except in Group III in which clearly measurable values for T_3 were obtained the quantities of iodine in T_3 were near the limit of detectability of the methods employed hence values of T_3 residues should be considered with caution in the case of Groups I and II The data leave no doubt however that an increase in both the proportion and absolute number of residues of T_3 occured in Group III

DISCUSSION

The present studies have provided unavailable information concerning the iodine thyroglobulin and iodoamino acid content of the human newborn in the early hours after birth and of the changes that have occurred after the first few weeks of life There are obvious difficulties encountered in conducting or interpreting a study of this type many of which cannot be surmonted First the studies must obviously be carried out in tissues of babies who have expired and the question could be raised therefore as to the effects of the underlying illness upon the results obtained Although this possibility cannot be excluded the infants from whom tissues had been obtained died of a variety of disorders some spontaneous and some traumatic (8) Moreover there is currently no information that would relate in a causative way the occurrence of a lethal illness and certain of the abnormalities that we have observed In addition the small amount of tissue available and its low iodine content created potential analytic difficulties but these were important only in the case of T_3 analysis in thyroids obtained during the first few hours after birth

A major finding of the present studies is the demonstration that the iodine concentration per unit weight of the thyroid is far lower in the early neonate than it is later in the neonatal period This can be explained in large part by the lower concentration of TG present in the early neonatal thyroid a finding that correlates well with lack of colloid seen on histologic examination as reported earlier (8) This phenomenon can result from the stimulation caused by TSH surge (10 4) few minutes after birth at the end of the TSH peak the thyroidal components gradually increase Most likely the release of the intrathyroidal stores explain the increased concentration of TG present in the cord blood (12) Moreover the role of an enhanced rate of TG proteolysis either antecedent to or coincident with birth is unknown Finally it is possible that the capacity of the fetal thyroid to synthesize thyroglobulin is limited and improves after birth although this cannot be studied

As shown in the analyses of Group III thyroids an increase in TG and iodine concentrations occurs between the first few days and the first few weeks of life Values for thyroid iodine concentration obtained in this group accord well with those previously reported (17) Nevertheless values for iodine concentration even in this group are below those found in the thyroid of the normal adult (6)

The second major finding of the present study relates to the iodine and iodoamino acid content of the TG itself The mean iodine content of TG was below the lower limit of the normal range in Group I thyroids increased into the normal range in Group II thyroids and was at the upper limit of the normal range in Group III thyroids (19) No explanation is available for this increase with increasing survival time in the iodine content of TG

What was most striking among the present results was the pattern of iodoamino acid content *in thyroglobulin* when related to its iodine content It is well known from studies of iodine-depleted rats (15) and of goitrous human thyroids (7) that the low levels of TG iodination are associated with an increased proportion of MIT relative to DIT a decrease in iodothyronine/iodotyrosine ratio and an increase in T_3/T_4 ratio The present studies of TG from neonatal thyroids revealed none of these relationships despite the wide variation in iodine contents of TG seen among the three groups studies Proportions of MIT were not particularly high nor were proportions of T_4 particularly low even in Group I thyroids Possibly the degree of lowering of iodine content in the neonatal thyroid being less severe than that in the TG of the iodine depleted rat or goitrous human thyroid is insufficient to elicit changes in iodoamino content of the type described above

The last puzzling finding is the transiently low content of T_3 found in the thyroid of the neonate *during the first hours of life however* T_4/T_3 ratios from Group I and II are close to the values found in the fetus (11) Ratio from the thyroids of Group III is slightly different if we consider these 3 values are representative of long survival neonates this ratio is lower than that found in the thyroid of adults (3) A similar lack of T_3 has been observed in the fetus and neonatal pigs (9) suggesting that the phenomenon observed in the present study may be general Our findings can be linked to the low concentration of T_3 found in cord blood in the neonates (1) and the T_3 serum increase observed few minutes after birth triggerd by the TSH surge could be due to an accelerated conversion of T_4 to T_3 the intra thyroidal stores are in suffisant amount to provide it The T_4 changes observed later in the serum correspond to the onset of the repleted stores in the thyroid

ALDOSTERONE AND SODIUM HOMEOSTASIS IN PRETERM INFANTS

J W HONOUR H B VALMAN and C H L SHACKLETON

From the Divisions of Clinical Chemistry and Perinatal Medicine Clinical Research Centre Harrow Middlesex U K

ABSTRACT Honour J W Valman H B and Shackleton C H L (Divisions of Clinical Chemistry and Perinatal Medicine Clinical Research Centre Harrow U K) Aldosterone and sodium homeostasis in preterm infants Acta Paediatr Scand 66 103 1977.—A specific mass spectrometric method was used for tetrahydroaldosterone determination in urine of preterm infants (26–34 weeks gestational age) up to 9 weeks of age Hyponatraemia during the first 2 weeks of life was associated with an excretion of tetrahydroaldosterone (5–50 μg/24 h) comparable with full term infants Excretion of tetrahydroaldosterone was significantly elevated in all infants studied during the third week of life (80–350 μg/24 h) and this was associated with establishment of positive sodium balance The excretion of tetrahydroaldosterone remained high for 2 or 3 weeks The results are discussed in relation to the development of renal tubules and control mechanisms for sodium homeostasis

KEY WORDS Preterm infants sodium homeostatis tetrahydroaldosterone excretion

Sulyok reported that plasma sodium levels in healthy preterm infants fall during the first 2 weeks of life reaching a minimum level (mean 133 mmol/l) on about the 17th day (21) A negative salt balance was observed during this period Thereafter a positive sodium balance was restored and plasma sodium levels returned to normal It has been generally accepted that these features of sodium homeostasis are caused by the immaturity of the renal tubules (21 22)

The role of aldosterone in the development of sodium homeostasis in preterm infants is not well understood Other investigators have assumed that the low aldosterone secretion rate during the first week of life (23) precluded a significant role for aldosterone in sodium retention during this period Continuous studies for longer periods have not been reported

A study of urinary tetrahydroaldosterone excretion during the first weeks of life in preterm infants is being undertaken in this laboratory A preliminary communication reported elevated tetrahydroaldosterone excretions in twin 14 day-old infants delivered at 29 weeks gestation (8) The values reported (60–225 μg/24 h) were greatly in excess of those found for normal full term infants in this study and by other investigators (13)

In the present report the aldosterone status has been studied in relation to the sodium balance of preterm infants of gestational ages 26–34 weeks

PATIENTS AND METHODS

Nine newborn infants of gestational age 26–34 weeks have been studied (Table 1)

All deliveries (except *Case 3*) were spontaneous and premature Infant *3* was born by elective Caesarian section carried out due to concern arising from rapidly rising maternal blood pressure Age was calculated from the mother's last menstrual period and confirmed by clinical examination (5) In general infants received breast milk collected from mothers in the maternity wards Commercial preparations where used were similar in electrolyte content to human milk Details of fluid and milk intake were recorded Twenty four hour specimens of urine were generally collected in plastic paediatric urine bags although in a few cases disposable napkins

ALDOSTERONE AND SODIUM HOMEOSTASIS IN PRETERM INFANTS

J W HONOUR H B VALMAN and C H L SHACKLETON

From the Divisions of Clinical Chemistry and Perinatal Medicine Clinical Research Centre Harrow Middlesex U K

ABSTRACT Honour J W Valman H B and Shackleton C H L (Divisions of Clinical Chemistry and Perinatal Medicine Clinical Research Centre Harrow U K) Aldosterone and sodium homeostasis in preterm infants Acta Paediatr Scand 66 103 1977.—A specific mass spectrometric method was used for tetrahydroaldosterone determination in urine of preterm infants (26–34 weeks gestational age) up to 9 weeks of age Hyponatraemia during the first 2 weeks of life was associated with an excretion of tetrahydroaldosterone (5–50 μg/24 h) comparable with full term infants Excretion of tetrahydroaldosterone was significantly elevated in all infants studied during the third week of life (80–350 μg/24 h) and this was associated with establishment of positive sodium balance The excretion of tetrahydroaldosterone remained high for 2 or 3 weeks The results are discussed in relation to the development of renal tubules and control mechanisms for sodium homeostasis

KEY WORDS Preterm infants sodium homeostatis tetrahydroaldosterone excretion

Sulyok reported that plasma sodium levels in healthy preterm infants fall during the first 2 weeks of life reaching a minimum level (mean 133 mmol/l) on about the 17th day (21) A negative salt balance was observed during this period Thereafter a positive sodium balance was restored and plasma sodium levels returned to normal It has been generally accepted that these features of sodium homeostasis are caused by the immaturity of the renal tubules (21 22)

The role of aldosterone in the development of sodium homeostasis in preterm infants is not well understood Other investigators have assumed that the low aldosterone secretion rate during the first week of life (23) precluded a significant role for aldosterone in sodium retention during this period Continuous studies for longer periods have not been reported

A study of urinary tetrahydroaldosterone excretion during the first weeks of life in preterm infants is being undertaken in this laboratory A preliminary communication reported elevated tetrahydroaldosterone excretions in twin 14 day old infants delivered at 29 weeks gestation (8) The values reported (60–225 μg/24 h) were greatly in excess of those found for normal full term infants in this study and by other investigators (13)

In the present report the aldosterone status has been studied in relation to the sodium balance of preterm infants of gestational ages 26–34 weeks

PATIENTS AND METHODS

Nine newborn infants of gestational age 26–34 weeks have been studied (Table 1)

All deliveries (except *Case 3*) were spontaneous and premature Infant *3* was born by elective Caesarian section carried out due to concern arising from rapidly rising maternal blood pressure Age was calculated from the mother s last menstrual period and confirmed by clinical examination (5) In general infants received breast milk collected from mothers in the maternity wards Commercial preparations where used were similar in electrolyte content to human milk Details of fluid and milk intake were recorded Twenty four hour specimens of urine were generally collected in plastic paediatric urine bags although in a few cases disposable napkins

were used In a separate study (to be published) we have shown similar steroid excretion patterns in urine collected in a bag for 24 h and an extract prepared by centrifugation of disposable napkins used during the next 24 h period Capillary blood samples were taken by heel puncture

Informed consent was obtained from the parents for execution of detailed sodium balance studies Male infants were selected because of the relative ease of obtaining accurate 24 h urine collections The normal range for plasma sodium concentration in full term infants at this hospital is 135–145 mmol/l and for the purpose of this study hyponatraemia was defined as a persistent concentration below this range

A weight loss after birth was observed in all infants with minimum weights recorded on the 4th or 5th day Birth weights were regained between days 7 and 18 (Table 1) The infants were discharged from hospital when they had reached a weight of 2 5–3 kg and subsequent progress has been uneventful

The prenatal and intrapartum histories of all mothers were closely scrutinised All were on unrestricted salt diets and received no diuretics during the later stages of pregnancy

Analytical methods

Sodium and potassium concentrations were determined simultaneously by twin channel flame photometry Lithium was added to the samples for use as internal standard

Urinary tetrahydroaldosterone was measured by a gas chromatographic mass spectrometric (GC–MS) method (9 16 17) This steroid is excreted in urine as a 3 glucosiduronate and had to be released from conjugation by enzymic hydrolysis (digestive juice of the snail *Helix pomatia*) An internal standard of 3β-*allo* tetrahydroaldosterone was added prior to steroid extraction on Amberlite XAD 2 resin columns The extracts were fractionated on small Sephadex LH 20 columns and methyloxime trimethylsilyl ethers were prepared of the fraction containing tetrahydroaldosterone The derivatives were analysed by GC MS using a Varian MAT 731 instrument in a selective ion monitoring mode The fragment ions of mass to charge ratio 638 (molecular ion M⁺) and 607 (M⁺−31) were alternately monitored at 1 sec intervals

The peak height of the *m/e* 607 ion of urinary tetrahydroaldosterone was measured relative to the peak height of the equivalent ion derived from the internal standard separated by gas chromatography The ion at *m/e* 638 was only monitored to confirm the specificity of the determination The results were calculated according to the formula

$$X = \frac{H_X}{H_S} \times R \times \frac{V}{U} \times S$$

RESULTS

Fig 1 illustrates the results of the detailed investigation of a male infant (*Case 1*) delivered at 27 weeks gestation On the 8th day of life urinary sodium excretion exceeded dietary intake by 1 mmol/kg/day A positive sodium balance was achieved by the 25th day of life Little significance can be attributed to the small positive balance observed on day 14 since in this study sodium loss other than in urine (e g faeces or sweat) were not determined Potassium intakes were around 3 2 mmol/kg/day and during the first 5 weeks of life potassium excretion did not exceed 1 6 mmol/kg/day with positive balances of around 2 0 mmol/kg/day On the 40th day potassium excretion rose to 2 6 mmol/kg/day and the ratio of urinary concentration of sodium to potassium fell to 0 46 from 1 30 on day 32 This infant was hyponatraemic and hyperkalaemic during the first 4 weeks of life thereafter the plasma sodium and potassium concentrations approached normal levels for full term infants The infant regained birth weight by day 17 Tetrahydroaldosterone excretion during the first 15 days of life remained within the upper limits of normal for a full term infant A significant rise was recorded between days 14 and 18 and levels remained high for 2–3 weeks

Figs 2 and 3 show similar data for infants delivered at 29 and 34 weeks gestation (*Case 2 and 3*) In both these patients positive sodium balance was observed by day 14 Unfortunately sodium balance studies and urinary tetrahydroaldosterone excretions were

RESULTS

Fig 1 illustrates the results of the detailed investigation of a male infant (*Case 1*) delivered at 27 weeks gestation On the 8th day of life urinary sodium excretion exceeded dietary intake by 1 mmol/kg/day A positive sodium balance was achieved by the 25th day of life Little significance can be attributed to the small positive balance observed on day 14 since in this study sodium loss other than in urine (e g faeces or sweat) were not determined Potassium intakes were around 3 2 mmol/kg/day and during the first 5 weeks of life potassium excretion did not exceed 1 6 mmol/kg/day with positive balances of around 2 0 mmol/kg/day On the 40th day potassium excretion rose to 2 6 mmol/kg/day and the ratio of urinary concentration of sodium to potassium fell to 0 46 from 1 30 on day 32 This infant was hyponatraemic and hyperkalaemic during the first 4 weeks of life thereafter the plasma sodium and potassium concentrations approached normal levels for full term infants The infant regained birth weight by day 17 Tetrahydroaldosterone excretion during the first 15 days of life remained within the upper limits of normal for a full term infant A significant rise was recorded between days 14 and 18 and levels remained high for 2–3 weeks

Figs 2 and 3 show similar data for infants delivered at 29 and 34 weeks gestation (*Case 2 and 3*) In both these patients positive sodium balance was observed by day 14 Unfortunately sodium balance studies and urinary tetrahydroaldosterone excretions were

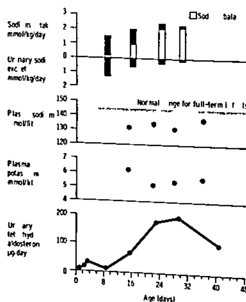

Fig 3 Postnatal values of sodium intake and excretion plasma electrolyte concentrations and urinary tetrahydroaldosterone in a preterm infant delivered at 34 weeks gestation (*Case 3*)

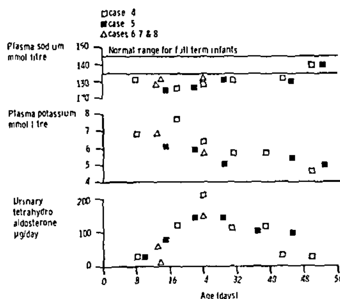

Fig 4 Urinary tetrahydroaldosterone excretion and plasma electrolyte concentrations in relation to postnatal age of 5 preterm infants

not obtained for *Case 2* during the first 2 weeks of life A normal daily intake of potassium for infant 2 was 2 7 mmol/kg/day Potassium balances on days 16 24 and 32 were 0 6 2 1 and 1 2 mmol/kg/day An increase in daily excretion of potassium was not observed but the ratio of sodium to potassium concentration in urine fell from 0 48 on day 16 to 0 09 at day 30 Urinary aldosterone excretions were determined on this patient and the levels were higher than those found for normal infants studied in this laboratory (1 to 2 µg/24 h) Plasma sodium concentrations increased during the period of study In one of the patients (*Case 2*) the plasma potassium concentration appeared also to increase but on this occasion results may have been unreliable because of haemolysis

Results of plasma electrolyte and tetrahydroaldosterone excretions for several other infants are illustrated in Fig 4 Since urinary extracts were occasionally obtained from disposable napkins it was not possible to determine sodium balance because urinary sodium was not assayed Tetrahydroaldosterone excretion in *Cases 4* and *5* show a similar pattern to that of the infants described above Values obtained during the first 10 days were low but a significant increase was observed after 15th day The plasma sodium concentrations were low in both infants during the first 6 weeks of life but approached normal values by the 8th week The trend of plasma potassium levels was reversed

Cases 6 7 and *8* were only studied for one day but the results were comparable to those obtained at the same age for the infants studied more extensively

Daily sodium balance studies and urinary tetrahydroaldosterone excretions were obtained for an infant born at 26 weeks gestational age (*Case 9*) The results obtained are illustrated in Fig 5 and demonstrate a severe negative balance throughout the study Sodium intake includes the sodium content of all fluids administered over the 24 h period Fluid injected intravenously varied considerably in volume and between the 5th and 8th day of life were particularly high Tetrahydroaldosterone excretion was extremely low during the first week of life and did not respond to the negative salt balance An increase was observed in the 2nd week although the high excretions ob

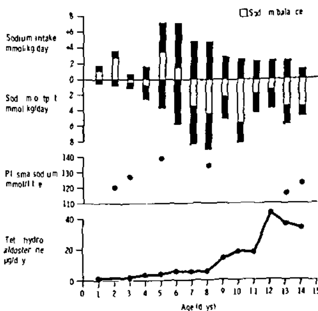

Fig 5 Daily changes in sodium intake and excretion in relation to plasma sodium concentrations and urinary tetrahydroaldosterone excretion The infant (*Case 9*) was delivered at 26 weeks gestation

tained in the other cases were not achieved This increased secretion of aldosterone was evidently insufficient to arrest the sodium loss and death occurred on the 15th day of life

DISCUSSION

Aldosterone can be synthesised by the foetal adrenal from early in gestion Dufau & Villee (6) achieved a synthesis of aldosterone from progesterone by adrenal homogenates from foetuses 15 weeks old and Pasqualini et al (16) demonstrated that perfusion of a 20 week old foetus with labelled corticosterone resulted in aldosterone synthesis It may therefore be concluded that viable preterm infants are capable of aldosterone synthesis A significant amount of aldosterone circulating in the full term foetus at birth is of foetal origin and relatively high levels persist in the newborn for several days (2 3)

Aldosterone catabolism is considered to be similar in fullterm neonates and adults since New and co-workers (13) found comparable proportions of urinary free aldosterone its 18 glucosiduronate and tetrahydroaldosterone glucosiduronate However the problems of determining aldosterone production are exacerbated when preterm infants are being studied since metabolising enzymes in the liver and kidney may be immature resulting in altered steroid catabolism Premature infants aged 33–75 days appear to excrete a disproportionately high amount of free aldosterone compared to the other aldosterone metabolites (13) The high tetrahydroaldosterone excretions demonstrated in the present study provide *in vivo* evidence for the capacity of preterm infants at a developmental age of 28 weeks gestation to catabolise aldosterone in a similar manner to an adult In one of our patients (*Case 2*) aldosterone (free plus 18 glucosiduronate) was determined in urine as well as tetrahydroaldosterone The ratio of tetrahydroaldosterone to aldosterone was generally greater than 20 1 which compares with a ratio of about 2 1 for the full term newborns studied by New et al (13) However our results are not directly comparable with those of New and co-workers who studied newborns only during the first 24 h of life when urine may include metabolites of maternal aldosterone Although the ratio of the individual aldosterone metabolites excreted by preterm infants full term infants and adults appears to be at variance there is no doubt that tetrahydroaldosterone is the major metabolite of aldosterone in preterm infants and must reflect aldosterone secretion

The urinary tetrahydroaldosterone excretion during the first week of life in premature infants were generally slightly higher than those found for full term neonates (14 19) and increased considerably around the 15th day Although the early tetrahydroaldosterone excretions are higher than adults when adjusted for body surface area the increase in aldosterone secretion suggests a transient period of mineralocorticoid deficiency after birth

The high renin activity in the first weeks of life of full term neonates reported by Kotchen et al (10) suggests a lower responsiveness of aldosterone synthesis to renin angiotensin stimulation during this period and may explain why aldosterone secretion is not significantly stimulated by hyponatraemia when associated with the presence of a negative salt balance Siegel et al (19) found a high level of plasma aldosterone in preterm infants during the first few days of life and state that this finding precludes aldosterone insufficiency being responsible for the sodium wasting and hyponatraemia observed If their patients had been studied for a longer period even higher plasma aldosterone levels would almost certainly have been found and their conclusions invalidated These authors have assumed that high aldosterone levels are synonomous with high activity High plasma aldosterone concentrations may reflect a compensation for lower response of the renal tubules to the hormone or are required to counteract an aldosterone antagonist The newborn synthesises many

steroids in large amounts which may antagonise the action of aldosterone on the renal tubules For example 16α hydroxyprogesterone has a natriuretic effect in adults (11) and while this particular steroid may not be responsible for opposing the activity of aldosterone in newborns many similar steroids are secreted by the adrenals in large amounts

It is not known whether the increased aldosterone secretion in the third week of life reflects a response to increased stimulation or to improvement in the ability of the adrenals to synthesise larger amounts The renal tubules are assumed to respond to aldosterone at this stage since a positive sodium balance is established with the consequent concentrations of sodium and potassium in plasma However the renal tubules cannot be responding optimally to aldosterone since sodium is still excreted in urine when plasma sodium concentration remains low and a direct renal exchange of sodium with potassium was not demonstrated until the 6th week of life Insufficient sodium reabsorption may be due to earlier maturation of renal glomeruli resulting in an imbalance between tubule and glomerular mass (7) Aperia et al (1) consider that the relatively high fractional sodium excretion in preterm infants may be attributed to an inadequate tubular surface area These investigators concluded that aldosterone was not important in tubular sodium reabsorption on the basis of the low aldosterone secretion rates reported by Weldon and co workers (23)

In spite of sodium retention the aldosterone secretion may subsequently continue to be high in response to the plasma sodium concentration remaining below normal or to hypertrophy of the *zona glomerulosa* The sodium balance figures reflect largely the amount of sodium used in growth From the third week of life the figures observed (1–2 mmol/kg/day) agree with the rates of accumulation of sodium by human foetuses in relation to gestation (18)

Further studies involving determinations of aldosterone metabolism and renin activity are required to resolve the outstanding problems of sodium regulation in infancy A method for the analysis of renin activity in small amounts of blood has recently been published by Dillon (4) and determinations of renin activity using this method are to be included in future investigations

ACKNOWLEDGEMENTS

We are indebted to Miss D Davis and the nursing staff of the Special Care Baby Unit Northwick Park Hospital for their co-operation in these studies The determinations of urinary aldosterone were kindly carried out by C E Horth of Searle Diagnostics

PLASMA TRIGLYCERIDE INCREASE AFTER ORAL FAT LOAD IN MALABSORPTION DURING EARLY CHILDHOOD

S P FALLSTRÖM C O NYGREN and R OLEGÅRD

From the Department of Paediatrics I East Hospital University of Goteborg Sweden

ABSTRACT Fallstrom S P Nygren C-O and Olegård R (Department of Paediatrics I East Hospital University of Goteborg Sweden) Plasma triglyceride increase after oral fat load in malabsorption during early childhood Acta Paediatr Scand 66 111 1977.—Plasma triglyceride (TG) levels were determined before and after a test meal of 2 g neutral fat per kg b w in 32 children with different malabsorption syndromes 8 children with transient growth retardation without demonstrable disease and in 29 controls The increase of plasma TG 120 min after the test meal was found to discriminate between children with malabsorption syndromes and controls during the studied age period 1 month–3 years In this respect it was superior to faecal fat determination Children with transient growth retardation who later spontaneously regained satisfactory growth although along a lower SD score than the initial one showed a TG increase after the test meal comparable to that of the controls

KEY WORDS Fat absorption test malabsorption coeliac disease cystic fibrosis growth retardation children

Utilisation of dietary fat requires digestion in the presence of bile salts and lipases at a suitable pH and transport through the instestinal mucosa Disturbed fat absorption occurs in several gastrointestinal diseases and determination of the fat absorption has become a valuable diagnostic tool It is usually accomplished by determination of the fat content in faeces collected during three or more days with the patient on a standardized diet the fat content in faeces often expressed as a fraction of consumed fat (2 6) However in small children quantitative collection of faeces during several days is laborious and in case of diarrhoea difficult to achieve Furthermore during infancy the coefficient of fat absorption varies with age and type of feeding (3 15) which must be considered in the evaluation of faecal fat content Under certain conditions the blood concentration of a lipid substance after a test meal containing the lipid in case is a measure of its absorption (10) Chylomicrographic and turbidometric estimation of the lipaemia after a test meal of neutral fat has been used mainly in experimental work (4 5 13) but because of methodological shortcomings (14) these methods have found little application in clinical work

Nowadays simple and accurate spectrophotometric methods for determination of the triglyceride (TG) concentration in plasma are available in most hospitals Therefore we have tested the value of plasma TG levels after oral fat load in the diagnosis of malabsorption in early childhood

MATERIAL

The following groups of children were studied

Controls Twentynine children aged 3 weeks to 20 months—14 of whom were less than 4 months of age without gastrointestinal symptoms and signs of infection All showed satisfactory growth and weight increase at the time of study and continued to do so at follow up controls later

Glutenenteropathy Twentyfive children aged 5 to 21 months with longstanding diarrhoea and/or failure to

PLASMA TRIGLYCERIDE INCREASE AFTER ORAL FAT LOAD IN MALABSORPTION DURING EARLY CHILDHOOD

S P FALLSTRÖM C O NYGREN and R OLEGÅRD

From the Department of Paediatrics I East Hospital University of Goteborg Sweden

ABSTRACT Fallstrom S P Nygren C-O and Olegård R (Department of Paediatrics I East Hospital University of Goteborg Sweden) Plasma triglyceride increase after oral fat load in malabsorption during early childhood Acta Paediatr Scand 66 111 1977.—Plasma triglyceride (TG) levels were determined before and after a test meal of 2 g neutral fat per kg b w in 32 children with different malabsorption syndromes 8 children with transient growth retardation without demonstrable disease and in 29 controls The increase of plasma TG 120 min after the test meal was found to discriminate between children with malabsorption syndromes and controls during the studied age period 1 month–3 years In this respect it was superior to faecal fat determination Children with transient growth retardation who later spontaneously regained satisfactory growth although along a lower SD score than the initial one showed a TG increase after the test meal comparable to that of the controls

KEY WORDS Fat absorption test malabsorption coeliac disease cystic fibrosis growth retardation children

Utilisation of dietary fat requires digestion in the presence of bile salts and lipases at a suitable pH and transport through the instestinal mucosa Disturbed fat absorption occurs in several gastrointestinal diseases and determination of the fat absorption has become a valuable diagnostic tool It is usually accomplished by determination of the fat content in faeces collected during three or more days with the patient on a standardized diet the fat content in faeces often expressed as a fraction of consumed fat (2 6) However in small children quantitative collection of faeces during several days is laborious and in case of diarrhoea difficult to achieve Furthermore during infancy the coefficient of fat absorption varies with age and type of feeding (3 15) which must be considered in the evaluation of faecal fat content Under certain conditions the blood concentration of a lipid substance after a test meal containing the lipid in case is a measure of its absorption (10) Chylomicrographic and turbidometric estimation of the lipaemia after a test meal of neutral fat has been used mainly in experimental work (4 5 13) but because of methodological shortcomings (14) these methods have found little application in clinical work

Nowadays simple and accurate spectrophotometric methods for determination of the triglyceride (TG) concentration in plasma are available in most hospitals Therefore we have tested the value of plasma TG levels after oral fat load in the diagnosis of malabsorption in early childhood

MATERIAL

The following groups of children were studied

Controls Twentynine children aged 3 weeks to 30 months—14 of whom were less than 4 months of age without gastrointestinal symptoms and signs of infection All showed satisfactory growth and weight increase at the time of study and continued to do so at follow up controls later

Glutenenteropathy Twentyfive children aged 5 to 21 months with longstanding diarrhoea and/or failure to

ute increase of the TG level after the test meal (Fig 1) In several patients with glutenenteropathy a delayed increase of the plasma TG concentration was found at 4 hours This finding may depend on delayed absorption of fat or retarded utilisation of the absorbed fat The significantly higher fasting TG level in gluten enteropathy than in the controls speaks in favour of the latter mechanism Investigations in this laboratory are in progress to evaluate this hypothesis

None of the controls older than four months had a TG increase at 2 hours less than 0 50 mmol/l and none of the children of that age with defined clinical malabsorption an increase exceeding 0 75 mmol/l (Table 1) Thus after 4 months of age an increase less than 0 50 mmol/l can be regarded as abnormal and values between 0 50 and 0 75 mmol/l as borderline Some of the controls younger than four months of age showed a less efficient fat absorption but their TG increase at 2 hours after the test meal always exceeded 0 30 mmol/l (Table 1) In the pathological groups which usually have to be considered during this early period i e infants with cystic fibrosis or hepatobiliary disease the increase was always poorer

Thus using a TG increase in plasma of 0 30 mmol and 0 50 mmol/l respectively at 2 hours after a test meal as the lower limits accepted for healthy infants before and after 4 months of age 30 out of 32 (94%) of children with different malabsorption syndromes were found to have abnormal triglyceride absorption The two remaining pathological cases fell in the borderline range but showed a lower percental increase than the age matched controls

Norman et al (8) found that in healthy infants the TG increase after a test meal exceeded 60% of the fasting level a value never reached by their pathological cases According to the present results this criterion is applicable after the age of four months while before that age a TG increase of 40% seems to be a better discriminating level Using the percental TG increase gave the same degree of overlapping between controls and children with glutenenteropathy as the absolute increase but different cases fell in the borderline range This depends on the fact that in glutenenteropathy not only the absolute TG increase but also the fasting TG level differs significantly from that of the controls Analysis of the relation between TG fasting level and TG increase at 2 hours indicates that at a fasting level below 0 90 mmol/l an absolute increase of 0 50 mmol per l is a preferable critical level while at higher fasting level a percental increase of 60% gives the best discrimination

The discriminating capacity of the TG absorption test compares favourably with that of the xylose test or the faecal fat determination (Table 3) It is especially noteworthy that the oral fat absorption test is superior to the much more time consuming and labourious faecal fat determination

In the group with so called transient growth retardation clinical and laboratory investigations did not reveal any gastroenterologic disease or other pathologic condition The result of the TG absorption test showing a TG increase equal to that in the age matched controls is in accordance with these findings The subsequent clinical course with spontaneous regain of adequate growth following a new growth SD score suggests that these children represent a normal variant of growth pattern (7)

Table 3 *Proportion of pathological results with the xylose test faecal fat determination and TG absorption test in glutenenteropathy*

Xylose	Faecal fat	TG absorption
19/25 (76%)	11/20 (55%)	23/25 (92%)

Using a TG increase at 2 hours of 0 50 mmol/l as discriminating level

of the fasting level In three of these infants the TG increase was less than 0 50 mmol per l and in another three infants between 0 50 and 0 75 mmol/l (Table 2) The percental increase was 44, 48 and 59% and 74 78 and 144% respectively There was no significant regression of the absolute or percental TG increase at 2 hours after the test meal upon age in the control group (r=0 01 and −0 21)

In children with glutenenteropathy the fasting TG level was significantly higher (p<0 01) than in the age matched controls but no or only slight increase of the TG level was found at 2 hours A delayed but moderate increase was found at 4 hours in 14 out of the 25 cases (Fig 1) The difference between the level at 2 hours and the fasting level varied between −0 31 and 0 73 mmol per l (−26 and 62 mg/100 ml) (Table 1 Fig 2) In the two cases with an increase exceeding 0 50 mmol/l the percental increases were 45 and 55% (Table 2) The percental increase was less than 58% of the initial value in all cases but one in which a low absolute increase of 0 42 mmol/l corresponded to a percental increase of 97% In patients with defective digestion the test meal gave only minute plasma TG changes, the TG increase at 2 hours never exceeding 0 20 mmol/l or 23% of the fasting level In contrast children with transient growth failured showed a TG increase of the same magnitude and with the same pattern as the controls (Fig 1–2 Table 1–2)

In Table 3 the TG absorption test the xylose test and the determination of faecal fat are compared with regard to their discriminating capacity in glutenenteropathy

DISCUSSION

In the present study the triglyceride (TG) level in plasma after a test meal was determined in connection with an analysis of the plasma fatty acid pattern, the results of which will presented in a subsequent paper The TG concentration was therefore calculated from a gas liquid chromatographic determination of the fatty acid pattern by the use of an internal standard As mentioned above the TG values obtained by this method are interchangeable with those determined by spectrophotometric methods in common use (9) Thus a TG absorption test as described here can easily be applied in clinical routine

In the controls a substantial increase of the plasma TG had occurred at 2 hours after the test meal while at 4 hours a return to or towards the fasting level had taken place in most of the children (Fig 1) In healthy adults the peak concentration of plasma lipids after a test meal has been reported to appear later appr after 4 hours and the increased level to be sustained longer (4 11) In these investigations on adults 1 5 g or less of butterfat per kg b w was given and the above mentioned differences may depend on the amounts and types of fat used (15) the Flora® margarine containing much more unsaturated fatty acids The possibility of physiological differences between young children and adults must be considered implying a more rapid fat resorption and utilisation in the former

Most controls younger than 4 months presented a TG increase after the test meal comparable to that in the older controls but in three of the younger infants the increase was smaller (Fig 1 2 and Table 2) This is in agreement with the reports on a less efficient fat absorption in very young infants (3 8) but the close relationship in healthy infants between age and TG increase after a test meal reported by Norman et al (8) could not be confirmed in the present study

Patients with digestive insufficiency (glutenenteropathy displayed a slow and mi

ute increase of the TG level after the test meal (Fig 1) In several patients with glutenenteropathy a delayed increase of the plasma TG concentration was found at 4 hours This finding may depend on delayed absorption of fat or retarded utilisation of the absorbed fat The significantly higher fasting TG level in gluten enteropathy than in the controls speaks in favour of the latter mechanism Investigations in this laboratory are in progress to evaluate this hypothesis

None of the controls older than four months had a TG increase at 2 hours less than 0 50 mmol/l and none of the children of that age with defined clinical malabsorption an increase exceeding 0 75 mmol/l (Table 1) Thus after 4 months of age an increase less than 0 50 mmol/l can be regarded as abnormal and values between 0 50 and 0 75 mmol/l as borderline Some of the controls younger than four months of age showed a less efficient fat absorption but their TG increase at 2 hours after the test meal always exceeded 0 30 mmol/l (Table 1) In the pathological groups which usually have to be considered during this early period i e infants with cystic fibrosis or hepatobiliary disease the increase was always poorer

NEONATAL ACIDOSIS ASSOCIATED WITH TRANSIENT METHYLMALONICACIDURIA AND VITAMIN B12 DEFICIENCY

A J WILLIAMS and J T IRELAND

From the Department of Child Health University of Liverpool and Department of Biochemistry Alder Hey Children s Hospital Eaton Road Liverpool England

ABSTRACT Williams A J and Ireland J T (Department of Child Health University of Liverpool and Department of Biochemistry Alder Hey Children s Hospital Liverpool England) Neonatal acidosis associated with transient methylmalonicaciduria and vitamin B 12 deficiency Acta Paediatr Scand 66 117 1977.—Investigation of a neonate presenting with a metabolic acidosis vomiting and an apnoeic attack revealed abnormal urinary excretion of methylmalonic acid (MMA) associated with a low serum vitamin B12 Restriction of dietary protein was followed by normalisation of acid base balance Reintroduction of normal daily protein intake did not precipitate further acidosis or increased excretion of MMA The transient methylmalonicaciduria was probably due to deficiency of vitamin B12

KEY WORDS Neonate acidosis methylmalonicaciduria vitamin B12 deficiency

The urinary excretion of abnormal amounts of methylmalonic acid (MMA) was reported first in association with vitamin B12 deficiency in adults (1 3) Congenital methylmalonicaciduria was subsequently described (9) and recognised to be due to disorders of methylmalonyl coenzyme A racemase (EC 5 1 99 1) (5) methylmalonyl CoA mutase (EC 5 4 99 2) (7) or to defective synthesis of the coenzyme 5 -deoxyadenosylcobalamin (11) which will secondarily impair methylmalonyl-CoA mutase activity A further disorder of vitamin B12 metabolism involving defective synthesis of methylcobalamin in addition to 5 -deoxadenosylcobalamin has also been reported (6) In those types associated with defective vitamin B 12 metabolism the biochemical abnormality is responsive to treatment with B 12 and the clinical course is usually milder (10)

CASE REPORT

Baby C was born to a primagravida mother by normal delivery at an estimated gestational age of 36 weeks with a birth weight of 3160 g The pregnancy had been unremarkable At birth the baby s condition was satisfactory Apgar score 8 at 1 min No abnormality was noted on routine examination Feeding was initially by gavage with expressed breast milk and Ostermilk Complete Formula Twitching of the limbs was noted on the second day and ascribed to hypocalcaemia (serum calcium 6 4 mg/dl) and hypomagnesaemia (serum magnesium 1 6 mg/dl) Despite calcium and magnesium supplementation and change of feed to Scientific Milk Adaptation (there being insufficient expressed breast milk) the twitching continued Cerebrospinal fluid was normal The twitching became worse on the fourth day and the infant had an apnoeic attack lasting about 30 sec followed by two vomits Subsequently she developed a metabolic acidosis unaccompanied by ketosis Urine pH remained between 4 0 and 4 5 The blood pH remained low at 7 05 for 7? hours during which time further investigation was undertaken Gas chromatographic analysis of a random urine specimen sent for screening purposes showed a large quantity of MMA (greater than 3400 μmol/l) No hyperglycinaemia was demonstrated

NEONATAL ACIDOSIS ASSOCIATED WITH TRANSIENT METHYLMALONICACIDURIA AND VITAMIN B12 DEFICIENCY

A J WILLIAMS and J T IRELAND

From the Department of Child Health University of Liverpool and Department of Biochemistry Alder Hey Children s Hospital Eaton Road Liverpool England

ABSTRACT Williams A J and Ireland J T (Department of Child Health University of Liverpool and Department of Biochemistry Alder Hey Children s Hospital Liverpool England) Neonatal acidosis associated with transient methylmalonicaciduria and vitamin B 12 deficiency Acta Paediatr Scand 66 117 1977.—Investigation of a neonate presenting with a metabolic acidosis vomiting and an apnoeic attack revealed abnormal urinary excretion of methylmalonic acid (MMA) associated with a low serum vitamin B12 Restriction of dietary protein was followed by normalisation of acid base balance Reintroduction of normal daily protein intake did not precipitate further acidosis or increased excretion of MMA The transient methylmalonicaciduria was probably due to deficiency of vitamin B12

KEY WORDS Neonate acidosis methylmalonicaciduria vitamin B12 deficiency

The urinary excretion of abnormal amounts of methylmalonic acid (MMA) was reported first in association with vitamin B12 deficiency in adults (1 3) Congenital methylmalonicaciduria was subsequently described (9) and recognised to be due to disorders of methyl malonyl coenzyme A racemase (EC 5 1 99 1) (5) methylmalonyl CoA mutase (EC 5 4 99 2) (7) or to defective synthesis of the coenzyme 5 -deoxyadenosylcobalamin (11) which will secondarily impair methylmalonyl-CoA mutase activity A further disorder of vitamin B12 metabolism involving defective synthesis of methylcobalamin in addition to 5 -deoxadenosylcobalamin has also been reported (6) In those types associated with defective vitamin B 12 metabolism the biochemical abnormality is responsive to treatment with B 12 and the clinical course is usually milder (10)

CASE REPORT

Baby C was born to a primagravida mother by normal delivery at an estimated gestational age of 36 weeks with a birth weight of 3 160 g The pregnancy had been unremarkable At birth the baby s condition was satisfactory Apgar score 8 at 1 min No abnormality was noted on routine examination Feeding was initially by gavage with expressed breast milk and Ostermilk Complete Formula Twitching of the limbs was noted on the second day and ascribed to hypocalcaemia (serum calcium 6 4 mg/dl) and hypomagnesaemia (serum magnesium 1 6 mg/dl) Despite calcium and magnesium supplementation and change of feed to Scientific Milk Adaptation (there being insufficient expressed breast milk) the twitching continued Cerebrospinal fluid was normal The twitching became worse on the fourth day and the infant had an apnoeic attack lasting about 30 sec followed by two vomits Subsequently she developed a metabolic acidosis unaccompanied by ketosis Urine pH remained between 4 0 and 4 5 The blood pH remained low at 7 05 for 72 hours during which time further investigation was undertaken Gas chromatographic analysis of a random urine specimen sent for screening purposes showed a large quantity of MMA (greater than 3 400 μmol/l) No hyperglycinaemia was demonstrated

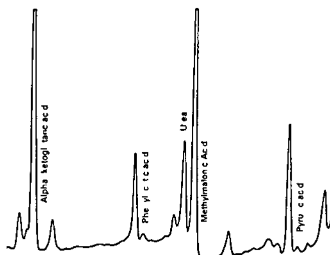

Fig 1 Gas liquid chromatogram First 24 hour specimen showing abnormal excretion of methylmalonic acid

and normal amounts of glycine were detected in the urine In view of the former finding dietary protein was with held and clear fluid feeds given There was dramatic relief of symptoms and of acidosis Analysis of a 24-hour urine collection on the following day confirmed the pre sence of excess MMA (Fig 1) though already the quant ity was markedly reduced the concentration of MMA being equivalent to a 24 hour output of 85 μmol This is outside normal limits (up to 42 5 μmol per day) After the acidosis corrected dietary protein was reintroduced at 0 5 g/kg body weight/day Thereafter in spite of increases in total protein intake no excess of MMA could be de tected in the urine The gas chromatogram of a 24 hour urine taken seven days after initial protein restriction with the infant on a protein intake of 1 g/kg/day and demonstrating a reduction of MMA excretion to normal is shown in (Fig 2) Acid base balance remained normal on a normal protein intake of 3 g/kg/day with no increase in MMA excretion This was attained at age 21 days and the infant was thriving in every way At no time was there any evidence of megaloblastic anaemia

DISCUSSION

Methylmalonicaciduria presenting in the ne onatal period is usually associated with a de vastating illness which has a significant mor tality Restriction of dietary protein alleviates acidosis though we were surprised to find no exacerbation with reinstitution of increasing amounts of protein The absence of ketosis and hyperglycinaemia together with the gen erally mild course of our patient and very modest MMA excretion were also factors suggesting that this was not congenital methyl malonicaciduria as previously described (9)

In children with a methylmalonyl CoA mutase defect or an inborn error of cobalamin metabolism one expects to see daily MMA ex cretion of 500 to 5 000 mg (4) though there has been one report of a child with homocystinuria and a defect in cobalamin metabolism in which MMA excretion was low (8) Our patient had rather high urinary levels of methionine and no increase in homocysteine excretion there by excluding this possibility The serum vita min B12 level done on day eight was 100 picog/ ml and although normal values at this age are ill defined this must be regarded as a low result (2) As the infant had already had by this time some artificial milk feeds containing B12 one might speculate that the cord blood B12 may have been even lower The mother s serum B 12 was 180 picog/ml which was out side the lower limit of normal for the labora tory There was no evidence for present or past maternal megaloblastic anaemia Three weeks after the initial B 12 estimation the baby s serum level had risen to 200 picog/ml

We are unaware of any evidence to suggest transient immaturity of the enzyme systems involved in the conversion of propionate and methylmalonate to succinate The mechanism producing the temporary and mild metabolic acidosis in our patient is probably vitamin B12 deficiency compromising the synthesis of the coenzyme 5 deoxyadenosylcobalamin and thus producing an accumulation of methyl malonate Even when artificial feeds were in troduced the occasional vomits may have led to inadequate vitamin B12 intake With the cessation of vomiting and gradual reintroduc

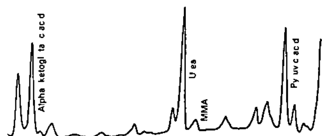

Fig 2 Gas liquid chromatogram 24 hour specimen col lected six days after Fig 1 Showing normal organic acid pattern

tion of dietary protein vitamin B12 levels increased sufficiently to ensure an adequate supply of 5 deoxyadenosylcobalamin The deficiency of vitamin B12 may have been secondary to relative maternal deficiency However cord B12 levels are usually higher than maternal levels at term (2) It is therefore possible that derangement of the B12 placental transport mechanism might account for the abnormal mother/infant B12 ratio seen here

CASE REPORT

MEDIUM CHAIN TRIGLYCERIDES FOR TREATMENT OF SPONTANEOUS NEONATAL CHYLOTHORAX

Lipid Analysis of the Chyle

B PEITERSEN and B BROCK JACOBSEN

From the University Clinic of Paediatrics Fuglebakken Copenhagen Denmark

ABSTRACT Peitersen B and Jacobsen B B (University Clinic of Paediatrics Fuglebakken Copenhagen Denmark) Medium chain triglycerides for treatment of spontaneous neonatal chylothorax Acta Paediatric Scand 66 121 1977.—Volume and contents of lipid and protein in the pleural fluid from a three weeks old girl with spontaneous chylothorax were studied (*a*) during parenteral nonfatty nutrition and later (*b*) during administration of a formula (Biosorbin®) containing medium chain triglycerides (MCT) The pleural fluid production could not be correlated to the treatment employed but suddenly ceased after 20 days management Triglyceride and total esterified fatty acid concentrations in pleural fluid were high on admission when feeded with human milk and chylomicrons and other lipoproteins were present in the chyle During parenteral treatment a pronounced decrease in pleural fluid concentrations of triglyceride and total fatty acids occurred concomitant with a disappearance of the chylomicrons During the following MCT diet a pronounced increase in triglyceride and total fatty acids concentrations appeared and the chylomicrons reappeared in the chyle The cholesterol and phospholipid concentrations in the pleural fluid showed only small changes during the different treatments No significant changes in protein and albumin concentrations of chyle were observed It is concluded that administration of the Biosorbin® MCT formula containing 87½% of the fat as MCT seems without value in the treatment of spontaneous neonatal chylothorax

KEY WORDS Spontaneous chylothorax medium chain triglycerides

Chylothorax is a serious complication in childhood mainly found in connection with thoracotomy thoracic trauma or tumors (13 19 20)

In the neonatal period spontaneous chylothorax occurs with no clear evidence of the aetiological factors (19 23 26) The usual assumption seems to be that congenital abnormities in the lymphatic system are the main cause (13 19)

Symptoms of chyloaccumulation in the pleural cavity may appear during the first weeks of life (4 19 23 26) The pleural effusion often persists for several weeks but can diminish spontaneously in a few weeks (4 18 19 26) During the last ten years the treatment of various diseases in the lymph system with medium chain triglycerides (MCT) has been acknowledged (10 21) Contrary to more long chained triglycerides MCT is transported directly into the portal system (12 21) bypassing the lymphatic pathways The conclusion has therefore been that a MCT diet would diminish the volume of lymph

KEY WORDS Spontaneous chylothorax medium chain triglycerides

Chylothorax is a serious complication in childhood mainly found in connection with thoracotomy thoracic trauma or tumors (13 19 20)

In the neonatal period spontaneous chylothorax occurs with no clear evidence of the aetiological factors (19 23 26) The usual assumption seems to be that congenital abnormities in the lymphatic system are the main cause (13 19)

Symptoms of chyloaccumulation in the pleural cavity may appear during the first weeks of life (4 19 23 26) The pleural effusion often persists for several weeks but can diminish spontaneously in a few weeks (4 18 19 26) During the last ten years the treatment of various diseases in the lymph system with medium chain triglycerides (MCT) has been acknowledged (10 21) Contrary to more long chained triglycerides MCT is transported directly into the portal system (12 21) bypassing the lymphatic pathways The conclusion has therefore been that a MCT diet would diminish the volume of lymph

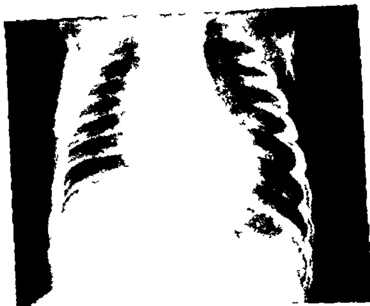

Fig 2 Chest X ray 2 month later completely normal

frozen until analysis Cholesterol (22) phospholipid (6) total fatty acids (8) and triglycerides (15) were determined later Lipoproteinelectrophoresis was performed according to Widme (25) and Frederickson (7) Finally analysis of total *protein* (1) and albumin (14) was made

RESULTS

Amount of lipids in pleural fluid is shown on Table 1 On *admission* to hospital when the child was given mother s milk the concentration of triglycerides and total esterified fatty acids was high compared with values measured later on during the treatment Lipoproteinelectrophoresis showed chylomicrons and other lipoproteins Under administration of the *parenteral* nonfatty treatment the pleural concentration of triglycerides and total fatty acids showed a distinct decrease and chylomicrons could no longer be detected During the following *MCT treatment* the pleural fluid again showed a pronounced increase in the triglyceride and total fatty acids concentration and chylomicrons reappeared The phospholipid and cholesterol concentrations showed only minimal changes during the different periods

No specific changes in the concentration of protein and albumin could be detected

During the MCT diet serumconcentrations of triglycerides cholesterol phospholipids and total fatty acids showed a falling tendency (Table 3) The serum albumin and hemoglobin concentration dropped as long as the pleural effusion persisted and blood transfusions were performed repeatedly

DISCUSSION

The clinical picture and the pleural fluid composition in our patient conform with criteria for a diagnosis of spontaneous neonatal chylothorax (4 13 19 26) It is a well known fact that pleural exudations from chylothorax patients are affected by change in lipidcontent of the diet (2 5 18 24)

Apparently only one report on MCT treatment of spontaneous neonatal chylothorax

Table 2 *Composition of Biosorbin per 100 g*

Supplement of vitamines and minerals in daily required amounts

Total calories		500
Protein	19 9 g	15% of calories
Carbohydrates	60 0 g	50% of calories
Fat	15 2 g MCT 2 5 g essential fatty acids	

80% of the essentiel fatty acids consist of long chained fatty acids

Fig 1 Chest X ray on admission to hospital shoving complete opacification of right hemithorax

through the thoracic duct (9 10 11 21) Three cases of chylothorax in childhood treated with MCT have been reported (3 9 16) and only one had spontaneous neonatal chylothorax

CASE REPORT

The patient is a 3 week-old girl born 3 weeks before term after a pregnancy and birth without any complications Birthweight was 2750 g The child was referred to hospital suffering from increasing respiratory difficulties the past two weeks On arrival she showed symptoms of severe respiratory distress and universal cyanosis Thorax X ray revealed a massive blurring in the right side of thorax and a distinct thrust of trachea to the left (Fig 1)

Intubation and ventilation in respirator were promptly performed and a permanent thoraxdrain was applied which at once removed about 250 ml milky pleural fluid where upon respiration soon became normal The pleural fluid contained numerous lymphocytes but no bacteria and the Sudan IV stain showed plenty of lipids The amount of fluid varied a great deal from day to day through out the whole period but perhaps varying function of the drain accounts for this The pleural effusion ceased completely after 14 days of MCT treatment The amount of chyle removed by drainage averaged 1250 ml The thorax drainage was frequently obstructed and had to be changed seven times before final removal after 24 days The first seven days the patient was treated with parenteral fluids (Table 1) and antibiotics

On day eight a MCT diet was instituted The Biosorbin® formula was used because we expected a long term treatment The composition of Biosorbin is seen from Table 2 Initially was given 80–85 g daily gradually increasing to 100–105 g After three month supplement of fruit vegetables meat and skimmed milk was added and Biosorbin® was discontinued after 6 month X rays of thorax normalized after one month (Fig 2) and the patient is now 15 month old in normal growth and development

METHODS

Samples of pleural effusion were collected in sterile containers with addition of 300 ml water or by direct aspiration with a sterile syringe The pleural fluid was deep-

Table 3 *Contents in serum of lipids during treatment*

Day of treatment	Treatment	Triglyceride (mmol/l)	Total fatty acids (mmol/l)	Cholesterol (mmol/l)	Phospholipids (mmol/l)
4	Parenteral	1 02	9 6	4 12	2 56
27	Biosorbin®	0 94		3 68	
50	-	0 95	8 6	3 24	2 20
90	-	0 49	7 8	3 40	2 07
180	Normal diet	0 84	11 6	3 38	2 28

* Parenteral treatment consists of glucose 5% electrolytes amino-acids albumin Bloodtransfusion were given 4 times during the first 27 days

can previously be found in litterature (3) In this report the effect of MCT on the pleural exudation was not recognized Lipid studies were not carried out

Two other studies of the effect of MCT in children with chylothorax have been reported (9 16) *In these patients the chylothorax* occured after thoracotomies, and the pleural effusion ceased after respectively 8 and 13 days MCT treatment

Lipid studies of the pleural fluid revealed *decrease in the concentration of triglyceride* and cholesterol concomitant with decrease in amount of pleural fluid In our case pleural effusion ceased after 14 days of MCT diet The pleural exudation tended to be smaller in the parenteral nutrition period than in the MCT period The cease of the pleural exudation might indicate a *spontaneous* recovery in accordance with natural cause of the disorder (18 19 26)

Therefore the lipid studies seems to be an important factor in evaluation of the MCT treatment The pronounced decrease in the triglyceride *and total fatty acids* concentrations in the pleural fluid during the *parenteral treatment period* suggests that intestinal lymph comprises a considerate part of the chyle in spontaneous neonatal chylothorax This theory is supported *by the fact that chylo*microns was not detected in this period Absence of changes in the cholesterol and phospholipid concentrations can be explained by the fact that cholesterol and phospholipid only exist in small amounts *in the membrane* of the chylomicrons (27)

During the *MCT treatment* the concentrations *of triglycerides and total fatty acids in*crease to levels seen on admission when the child *was feeded with human milk* These findings indicate that the administered Biosorbin in part is resorbed via the intestinal lymph *The small amount of long chained* essential fatty acids in Biosorbin could be one reason for this In the previous reports more than 95% of the fat content was comprised of MCT (9 16) We were prepared for a prolonged period of treatment and for this reason we used Biosorbin® formula containing essential fatty acid vitamins proteins etc

Previous reports describing favourable effects of MCT diet all deal with patients having posttraumatic chylothorax (9 11 16) while Brodman et al (3) did not observe any effect of MCT treatment in spontaneous neonatal *chylothorax The fact that the fat content in* the pleural fluid is significantly higher in posttraumatic chylothorax (18 26) may be due to a different pathogenesis in the cases and can possibly explain the lack of effect of MCT treatment in spontaneous neonatal chylothorax

We find like others (3 17) that rational treatment of patients with *spontaneous neonatal chylothorax* should consist of continuous *drainage of thorax—or repeated thoracocentesis*—combined with a parenteral nutrition with a sufficient supplement of calories proteins vitamins liquid and essential fatty acids, whereas MCT formula containing 87½% of the fat as MCT seems without effect

The annual meeting of the Association for Pediatric Education in Europe will be held *in UPPSALA (Sweden)* during the period June 22–24 1977 The principal topic will be Pediatric Education outside the hospital

Requests for information should be sent to Professor S Sjölin Department of Paediatrics University Hospital S 75014 Uppsala Sweden

Preparation of Manuscripts

tributors are requested to pay particular attention the following rules governing the preparation of ...scripts *Failure to follow these rules is a frequent ... of delay in the publication of articles and may ... in rejection of otherwise acceptable manuscripts*

Manuscripts should be sent, in duplicate, to the office of the Managing Editor Professor C G Berg... ...rand, Department of Paediatrics, Malmo Allmänna Sjukhus, S-214 01 Malmö Sweden, mailed flat and transmitted by first class mail They should be double spaced, typewritten on one side of the paper with wide margins Authors should exercise particular care in the preparation, notation and description of figures and tables. Each table must be accompanied by a descriptive title typed above the table to which it refers. A suitable legend must be provided for each figure. Oversized original illustrations should be photographed and a print on glossy paper submitted A separate *title page* is necessary and should bear a) the title b) the initials and names of the authors c) the institution of origin Below the list of *references* the principal author should state his address to which the proofs are to be sent

A short *abstract* not exceeding 200 words must accompany each manuscript informing about problem, methods results and conclusions Unexplained abbreviations and references are not allowed The abstract must be typed on a separate sheet and styled as illustrated

ABSTRACT Kohler L. and Holst, K (Department of Paediatrics University Hospital Lund Sweden) Dental health of four year-old children Acta Pædiatr Scand 00

An unselected population of 1 567 four year-old children

KEY WORDS Pre-school children caries gingivitis

A *summary* is usually not necessary but may be allowed if the author (or the Editor) finds it essential A summary should be typed immediately after "discussion"

References to the literature should be limited to those quoted by the author The reference list should be arranged alphabetically and numbered giving name of author (authors) initials full title of paper name of journal abbreviated in accordance with the style of *Index Medicus (New Series)* followed by the volume number page number and year *In this system of abbreviation periods are omitted*

1 Brecher O & Stohlman, F., Jr Humoral factors in erythropoietin *In* L. M Tocantins & R Penn (eds) *Progress in hematology* Grune & Stratton, New York 1959 p 110

2. Smith C. A. *The physiology of the newborn infant* Thomas, Springfield Ill 1967 3rd ed vol 2, p 120

3 Vedra, B & Ulrych, J.. Anaerobiosis in normal and asphyxiated premature newborns. 2. Four approaches *Acta Paediatr Scand* 49 129 1960.

Italics are marked in the manuscript by underlining.

Abbreviations must conform to accepted standards. When in doubt authors are advised to consult a recent issue of the Journal The SI system should be used Laboratory slang, clinical jargon and colloquialisms must be avoided

Proofs and Reprints Galley proofs will be sent to the principal author by the printer The master proof should be returned to the Managing Editor together with the manuscript within three days and by air mail if received by air mail Reprints of articles published must be ordered by separate application from *Almqvist & Wiksell S 751 81 Uppsala Sweden* to whom cheques money orders and drafts should be made payable

Manuscripts books for review and correspondence relating to the editorial management should be sent to the Managing Editor Department of Paediatrics Malmö Allmänna Sjukhus S-214 01 Malmö Sweden. Published manuscripts are not returned unless requested
